Corporate Governance and Business Sector Scenarios. Emerging Issues

Monographs and Essays Section

Corporate Governance is an interdisciplinary, contemporary and continuously evolving research strand.

The objective of the Series of publications Corporate Governance and Business Sector Scenarios is to offer to students, professionals and scholars the opportunity to reflect and discuss upon emerging issues in research. We intend to complete the existing panorama of numerous, mainly Anglo-Saxon publications, focusing on the Italian context, to be studied in comparative terms with respect to other countries.

The section monographs and essays publishes research presented to the Scientific Community during conferences and/or subjected to peer review.

Volume presentation

The emergence of creative industries as a distinct economic sector is easy to be located in the recent past. Whilst creativity always played a role in economy, debates on its significance, terminology and definitions started soon after World War II, intensified during the second half of the last century, and remain intense to the present day.

The difficulty to 'place' economic activities stemming from culture and creativity in a fairly comprehensive and intelligible context has prevented researchers and policy makers from coming to shared conclusions on definition criteria. The terminology-related confusion reached the peak at the end of the nineties when 'creative industries' superseded 'cultural industries', which had been until then a widely-agreed term for cultural policies at the national and the international level.

In the light of the intense academic debate developed around the cultural/creative industries, the first part of this book analyses tensions and debates around the diverging definitions, as well as some peculiar characteristics of these industries. The effects of application of different classification schemes in the mapping of the sector's boundaries are discussed, to illustrate the difficulties culture faces while competing with other sectors for funding within European economic policy frameworks.

In the second part, the spatial dimension of creativity is tackled by critically analysing the concept of creative clusters, the relationships of creative industries with the urban *milieu*, and the complex linkages with urban and regional planning and policies. It is argued that difficulties of studying creative clusters from a spatial perspective are related to the existence of conceptual problems as well as to the methodological awkwardness in facing the complexity of this issue. Creative clusters dynamics are illustrated with a case study in Greater Rome, thanks to the availability for this area of a detailed data-set.

Rome, 15 September 2019

Introduction

The so-called cultural turn in economic geography of the last three decades has gradually brought to the forefront a topic often overlooked by economic geography and by social sciences alike: the surge of economic activities underpinning the cultural and creative domains. The cultural turn is intrinsically linked to the gradual juxtaposing of the post-industrial, knowledge-based, global capitalist economy, with the emergent creative economy. In the new context, as James, Martin and Sunley (2006) affirm, the socio-cultural foundations of economic success (and failure) started to become apparent at multiple spatial scales.

The tendency towards the dispersion of productive activities emerged with the economic globalization and the advent of telematics has fuelled, over the last fifty years, processes that have yielded great impact on the structure of urban areas over the world. While the production exceeds national boundaries generating the expansion of global networks of affiliates and subsidiary companies, services tend to be concentrated in a limited number of cities, well known as 'global cities' (Sassen, 2001). The 'global cities', as theorized by Sassen, are characterized by concentrations of highly qualified services in different sectors that become vectors of the so-called metropolisation process. This process is primarily understood in terms of spatial dynamics of functions induced and, at the same time, derived by globalization. Conceptually different viewpoints refer to alternative denominations such as 'world city', 'world metropolis', 'international metropolis' (Hall, 1998; Taylor, 2004), where the main emphasis is given on understanding the place and the role played by a given city, in relation to others, in a globalized world scenario. These viewpoints can be addressed on two differing, yet, closely interrelated levels: on the first level, we look into the urban systems as located in the sphere of national and international competition for the purpose of tracking and scaling the hierarchy levels; on the second level, we look into their impact over the activities/functions and land uses within each metropolitan area. In this regard, the core issues to be dealt with include the transformation of productive systems and the identification of new specialized metropolitan functions, the new divisions and spatial reconfigurations of labour and the deriving physical transformation and renewed relations between parts of the city. These issues cover a broad spectrum of research, bringing together methods inherited from

the fields of urban economy, economic geography and endogenous growth theory (Sassen, 2001, 1996; Hall, 1988, 1993; King, 1990; Castells, 1996; Mittelmann, 1996; Ishida, 2000; Taylor, 2007; Tunas, 2010).

In this context, it is easy to figure out why topics such as creativity, creative class, and creative cities, have increasingly gained importance in research agendas of many geographers, regional scientists, and sociologists (Crewe, 1996; Banks et al., 2000; Coe, 2000; Leyshon, 2011). The cultural and creative industries represent one of the most important growth and employment sectors in advanced post-industrial countries and have played a major role in economic regeneration of previously deindustrialised local economies. These industries include: the arts; the media (e.g. films, television, music recording, publishing); fashionable consumer goods sectors (e.g. clothing, furniture, jewellery); services (e.g. advertising, tourism, entertainment); a wide range of creative professions (e.g. architecture, graphic arts, web-page design); and collective cultural consumption facilities (e.g. museums, art galleries, concert halls). The cultural and creative industries are characterised by the blurring of the symbolic and utilitarian functions of the products (Scott, 2010).

The rise of awareness about the economic significance of creativity in a globalized world has gone hand in hand with the affirmation of the term 'creative industries', often used interchangeably to the term 'cultural industries'. Notwithstanding the broad literature on the subject covering the evolution of the two 'creatively intertwined' terms (O'Connor, 1999; Towse, 2000; Cunningham, 2001; Flew, 2002; Hesmondhalgh, 2002; Caust, 2003; Hesmondhalgh and Pratt, 2005), the structural and organizational characteristics of the creative industries and the complex relationship between creativity on the one hand and society and economy on the other (Mommaas, 2004; Garnham, 2005; Pratt, 2005; 2011; Hesmondhalgh, 2007; Galloway and Dunlop, 2007; Evans, 2009; Scott, 2010; Flew, 2010), there is a blatant lack of convergence about key issues such as the existence of an univocal definition and a widely agreed theoretical basis enabling for an unambiguous delimitation of the sector boundaries. These incongruences, in turn, greatly affect public policies, through ill-suited sectorial objectives within economic agendas that have other priorities.

As a matter of fact, the topic is dominated, both at academic and at political level, by a terminological muddle that has fuelled, over the last decades, a prolific but confusing and inefficient debate in terms of economic policy and regional planning outcomes. Writing about the shift from 'cultural' to 'creative', Pratt (2011a) points at the inherent weakness of the term 'creative industry', arguing that '... *all industries are creative*' and that it is not possible to distinguish between, for example, scientific and cultural

innovation. Other scholars affirm that '... *all industries are cultural*' because the goods and services they produce have cultural relevance (Mato, 2009).

Cunningham (2001) considers that the term 'cultural industries' is already superseded through the advent of digital technology. He argues that new types of creative applications assume that the public are no longer reliant neither on the big corporation mass-produced entertainment (film, broadcasting, music) nor on real-time public consumption (arts), which are the 'traditional' components of cultural industries. On the other hand, Hesmondhalgh (2007) considers that the term 'creative industries' merely bypasses the cultural dimension, thus ignoring fundamental characteristics of the cultural production such as the symbolic and the social meaning.

Adorno and Horkheimer, who coined the term 'culture industry' in the '40s, would be perhaps relieved by the drift on the terminology: 'To speak of culture was always contrary to culture. Culture as a common denominator already contains in embryo that schematization and process of cataloguing and classification which bring culture within the sphere of administration' (Adorno and Horkheimer 1979/1947). Indeed, today there is less talk about culture in policy documents, whilst creativity, creative industries, creative occupations, creative clusters, are more pervasive terms. It has been widely argued that this shift in the terminology was not neutral (Cunningham, 2002; Hesmondhalgh and Pratt, 2005); it served to disjoin the 'creative industries' from those cultural productions that in order to be viable necessitate the 'visible hand' (public or private), defined by Dick Netzer (1978) as 'The Subsidized Muse'.

Most of the components of creative industries classification schemes adopted by national and international organizations for policy development purposes fall within the remit of the 'traditional' cultural domain. Creative industries encompass economic activities in the sectors of arts, media and publishing, including some typically creative activities such as design, architecture, advertising, or computer games. Classification schemes, often related to the structure of the statistical data, reckon with the fact that cultural categories are highly inhomogeneous and in part invisible to data collection (Girard, 1982). When looking at different classifications, the most striking feature is the inclusion or exclusion of entire groups of activities, according to the position they hold in a virtual matrix defined by *categories* axis (arts - cultural industries - creative industries) and a value chain axis (creation – production – distribution). Generally the 'mobile' parts concern categories falling within the creative industries/production domain, like design, style or software, or related to the heritage, such as the cultural tourism (see Figure 1.1 in p. 24). As a result, features on creative employment, value added or share in the GDP, placed in the first pages of many policy reports, hardly match.

In the ESSnet Culture 2009 final report (2012) the EU has opted for the disjointed term 'cultural and creative industries', obviating ambiguities in labelling some of the sub-sectors. But tensions and awkwardness about terminology are far from being over. Whilst international operating frameworks such as 'ESSnet Culture' or 'UNESCO framework for cultural statistics' are entitled after 'culture', almost all european and national mapping documents have accomplished the conversion to 'creative'¹. The EU program 'Creative Europe' (ex 'Culture Program') finances (with fewer resources in comparison to other sectorial-specific funding programmes) 'traditional' cultural activities². Creative industries are instead identified with the 'knowledge economy' driven by the 'digital' technologies. As such, they can draw upon other segments of the Structural Funds, where greater resources are allocated.

The commitment to positioning the creative industries at the forefront of economic competitiveness does not release researchers and policy makers from the duty to understand what will be the impact of the recent turn in economic and cultural policies. The lack of reflexivity, argues Garngham (2005), '... it disguises the very real contradictions and empirical weaknesses of the theoretical analyses it mobilises, and by so doing helps to mobilise a very disparate and often potentially antagonistic coalition of interests around a given policy thrust. It assumes that we already know, and thus can take for granted, what the creative industries are, why they are important and thus merit supporting policy initiatives'.

By now the creative sector embodied at its best by the cultural industries is very fashionable in the academia and in the political scene. Its growing importance for the modern economy and for its post-ideological administrators cannot pass unnoticed. There is plenty of enthusiasm about the sector, both at international and national policy-making levels, to tap into its development potentials, 'to unlock the full power of creativity' upon the devastations of the recent economic crisis (European Commission, 2010b). Yet, there is one thing that risks to go unnoticed in the hype about the creative sector: the risk that beyond mere rhetoric about 'creative cities', 'creative industry', 'creative technology' lurks little of real understanding of what the concept really means, of the multiple dimensions it stands for. Pratt (2011b) argues that '... *it is debatable whether a depth of understanding of*

the creative/cultural industries has been achieved. There remain a number of problematic relationships that are not fully understood: public and private, formal and informal, production and consumption, commercial and non-commercial...'.

In this endeavour the relatively large symbolic aura of the concept of creative/cultural industries ought to be properly taken into account so as to avoid distortion in its perception. Cultural industries are often defined in terms of their symbolic meaning (O'Connor, 1999), and according to the notion of 'use value' (Bilton and Leary, 2004; Martin, 2004). It is the communication of ideas rather than the functional value that really counts for the use of symbolic goods and services. This falls very much in line with the sociological insights of Luhmann's grand theory of 'society as communication' ('only what is communicated exists' - Luhmann, 1984). Consequently, all those activities that have as their final aim the communication of 'representative production', that is, of books, films, theatrical plays or music are considered to be part of the cultural industries. On the other side activities such as fashion design, advertising and architecture, even though they produce a highly symbolic content, yet do so by putting functionality as the first in line, are generally not considered as cultural industries. What these activities share in common, is that they all are about 'personal experiences'. They create consumer demand by feeding 'distinction' (Bourdieu, 1984) and by feeding on distinction. In so doing, they reduce consumer's sensitivity towards price by stretching from pure luxury to functional goods (Evans, 2009).

In the light of the intense academic debate developed around the cultural and creative industries, the first part of this book analyses tensions and debates around the diverging definitions, as well as some peculiar characteristics of these industries and their multiple relationships with the urban context. The effects of application of different classification schemes in the mapping of the sector's boundaries are discussed, to illustrate the difficulties culture faces while competing with other sectors for funding within European economic policy frameworks.

In the second part, the spatial dimension of creativity is tackled by critically analysing the concept of creative clusters, the relationships of creative industries with the urban *milieu* and the metropolization process, and the complex linkages with urban and regional planning and policies. It is argued that difficulties of studying creative clusters from a spatial perspective are related to the existence of conceptual problems as well as to the methodological awkwardness in facing the complexity of this issue. Creative clusters dynamics are illustrated with a case study in Greater Rome, thanks to the availability for this area of a detailed data-set.

Part I

Cultural or creative industries? A long-lasting debate

CHAPTER 1

History and definitions

The concept of creative industries is closely related to that of cultural industries. Almost all of the academic contributions dealing with these issues quote a writing of 1944 by marxist philosophers Theodor Adorno and Max Horkheimer, where the term 'culture industry' appears for the first time to emphasize what it was perceived as a contradiction between culture and industry. Heavy quotation perhaps is due to the fact that authors criticized the drift of culture on the sidelines of an epochal technological revolution; today, in the midst of the digital revolution, some of their concerns still appear updated.

Culture industry was about new industries of mass reproduction and distribution – film, sound recording, mass circulation dailies, popular prints, radio broadcasting – as opposed to the 'arts' – visual and performing arts, museums and galleries. According to Adorno and Horkheimer the Fordist factory system moved into the realm of culture: the producers of culture became alienated wageworkers, the artist workshops turned into factories headed by the big corporations. Thus, culture industry was rooted in the post War system of monopoly capitalism, exercising total control over the masses through mass media powered by modern industrial techniques.

The so-called 'high arts' defined by Dick Netzer (1978) as 'subsidized muse' remain at the origin of tensions that today concern the capability to measure the economic weight of culture. Cultural needs satisfied by the subsidized muse are different from those produced and distributed through the market. There is convergence on the fact that market cannot ensure the efficient allocation of resources for the creation of cultural products and services related to the sphere of high arts (Valentino, 2012). Notwithstanding, these make up the indisputable core of almost all sectorial classifications.

Market failure is the logic behind state support for the arts. During the 1940s Keynes himself, as head of the Committee for Encouragement of Music and the Arts (CEMA), contributed to the process of 'nationalization', legitimized during the post-war years with the establishment of the Arts Council of Great Britain (Galloway and Dunlop, 2007). The assumption of market failure also justifies many of the international declarations and conventions, such as those of the United Nations Educational, Scientific and Cultural Organisation (UNESCO).

During the 1970s and 1980s a new awareness emerged that cultural industries needed to be part of national cultural policies. France, reacting to US pressure on access to new markets for cultural trade exercised through the General Agreement on Tariffs and Trade (GATT), was the first nation to elaborate in the early 1980s a cultural public policy aimed at assisting the commercial sector (Towse, 2000; Flew, 2002). It was argued that, whilst a minority of cultural activities related to arts absorbed all the attention, the vast majority of consumed cultural products produced by the commercial sector could not be simply left to fend for themselves (Girard, 1972; 1982).

The Greater London Council (GLC) and other UK city councils took up these themes during the 1980s, establishing cultural policies at the local level. A remarkable work in adapting the notion of cultural industry to industrial policy making, was conducted by Garnham (1987; 1990) and Williams (1981), exponents of the school of political economy in UK. Their central argument was that under capitalism culture was produced as a commodity, and as such, it was subject to the logic and the contradictions of this production system. Garnham based his analysis of the cultural industries on the rejection of the idealist traditions of existing state support for culture and, contextually, the awareness of the fact that most people's cultural needs were already being met by the market and not by state 'subsidized muse' (Garnham, 1990). The crucial point was that art and the market are not antagonistic to each other: the market is an efficient way of allocating resources and reflecting choice. Therefore, cultural goods and services are to be distributed following the audience demand. Concerns emerged on the fact that there was not enough insight of how, by whom and under what conditions culture was produced, as detailed analysis was almost absent. This materialist vision of culture, seen to be completely reducible to the needs of 'capital' and the 'ruling class', reminds of post war Adorno and Horkheimer warnings, recalling the intrinsic contraposition between 'high arts' and commercial culture.

The experiments in France and Britain during the 1980s were a response to the national cultural policies centred on the arts and heritage and on subsidies to artists and producing institutions. This conceptual shift from 'culture industry' to 'cultural industries' represented a new approach to cultural policy (Bianchini and Parkinson, 1993). The commercial production of culture was addressed using economic and statistical tools (value-chains, employment mapping) and focusing on how the sector as a whole worked, including non-creative activities. In so doing, a better understanding was reached, of the connections between technologies of production and distribution, changing business models, the emergent connections between symbolic and informational goods, and between culture and communications systems (Hesmondhalgh, 2002; 2007). This understanding was at the basis of different policy initiatives by the Council of Europe and UNESCO, aimed to analyse the structure of cultural industries and create frameworks for assessing its socio-economic effects (Garnham, 1990).

The 1990s marked a new development stage for cultural policy and the cultural industries in particular, as a new category 'creative industries', busted into the scene. The 'formal' origins of the terminology are to be found in the Britain Government's establishment of a Creative Industries Task Force in 1997. For the first time the cutural sector was elevated at national policy, shifting the term to 'creative industries' and linking it to the concept of 'knowledge economy'.

After the election victory of the British Labour Party in 1997, the Department of National Heritage became the Department of Culture, Media and Sport (DCMS). In 1998 a Creative Industries Mapping document was produced, which gave a definition of creative industries that enhanced commercially motivated activities if compared to the exclusively 'artistic' ones. These industries were considered at the bases of economic development, urban regeneration and regional industrial diversification (Creative Industries Task force, 1998). Complemented by optimistic employment and wealth creation statistics, the DCMSs 'handy definition' introduced a list of 13 sub-sectors with clear links to statistical data sources. The use of the term 'creative industry' it was presented as a purely pragmatic move in order to facilitate access to funding; since the word 'culture' was too reminiscent of the 'arts' and thus not about economics at all, it should better been avoided (Cunningham, 2002; Hesmondhalgh and Pratt, 2005).

The DCMSs Mapping Document defines as creative industries those 'which have their origin in individual creativity, skill and talent and which have a potential for wealth and job creation through the generation and exploitation of intellectual *property*' (Creative Industries Task force, 1998). According to this definition the creative industries include: advertising, architecture, arts and antique markets, computer and video games, crafts, design, designer fashion, film and video, music, performing arts, publishing, software, television and radio. This definition excludes the heritage sector, archives, museums, libraries, tourism and sport although they remain part of the DCMS remit (De Propris et al., 2009). In UK this framework it was widely used by local authorities, development agencies, arts organisations and consultancies, to place cultural industry strategies at the heart of local and regional economic strategies. The mapping document, conceived as a toolkit for measuring the economic impact of 'creative industries', had a huge impact worldwide, as witnessed by proliferation of similar reports in other countries (KEA, 2006; UNCTAD, 2013; UNESCO-UNDP, 2013).

Garnham (2005) argues that the shift in terminology from cultural to creative industries was not a mere change of labels but there were both important theoretical and policy implications. He criticized the inclusion of 'software' within the creative categories, to make the statistics look more impressive and the over-inflated connection with the 'dot-com' world of 'information' and 'knowledge' economy. In the same line of criticism is positioned Pratt (2005), arguing that the information or knowledge involved in creative industries, science, R&D, business-to-business services are very different from each other, and Healy (2002a), which affirms that tying together under the 'creative' umbrella a whole range of activities and businesses covered by intellectual property in some form – design, trademark, copyright and patents, is not useful and might be confusing. Garnham (2005) also suggests that the concern with intellectual property rights is an attempt to overcome one of the key restrictions on profitability in the cultural industries: the tendency of cultural goods to become public goods.

Unlike the GLC's policy, that had emphasised the cultural sector as a whole, DCMS definition struggled to establish clear boundaries. According to this definition, creative industry relied on entrepreneurial creativity generating intellectual property rights, where 'creative' was considered a quality which is exploited by people that possess 'individual creativity, skill and talent' (Creative Industries Task force, 1998). The lack of reference to a specific cultural or artistic dimension makes it difficult to distinguish between what is to be considered 'creative' in this sector with respect to the others. The list of creative industries, framed within an economic agenda that had nothing to do with traditional cultural policy, included the 'arts', the 'classic' cultural industries and creative industries such as design, fashion and, more controversially, 'software'. As it was easy to be expected, ambiguities provoked criticism (Reeves, 2002; Selwood, 2002; 2004) that, however, did not

arrest the commitment to ensure to the 'creative industries' a theoretical legitimacy (Cunningham, 2002; 2004; Flew, 2002; Hartley, 2005).

Despite the shift in terminology, the subsidized muse remains a constant presence in classification schemes of creative industries, although quantitatively irrelevant. Contextually, they account for the vast majority of national and local government spending in culture (Feist, 2001). The centrality of 'the arts' to national governments cultural policies as well as to international policy platforms appears in contradiction with today's claims for the universality of creativity. This may be one of the reasons why Pratt (2011a) writes about the notion of 'culture as ornament', albeit justified by its potential instrumental value.

Undoubtedly the arts constitute a problematic node for classification schemes since it is not easy to frame them as industry categories. Some authors exclude arts from the 'list' of cultural industries (Garnham, 1990; Towse, 2003), others try to separate the flavours, by 'downgrading' the category for the purposes of classification.

David Hesmondhalgh considers arts as 'peripheral cultural industries' because they engage in semi-industrial or nonindustrial methods. Instead, he focuses on 'the core cultural industries' that '... *deal with the industrial production and circulation of texts [the production of social meaning] and are centrally reliant on the work of symbol creators*'. Core cultural industries include: advertising and marketing, broadcasting, film industries, internet industry, music industries (recording, publishing and live performance), print and publishing, video and computer games (Hesmondhalgh, 2002). By setting aside a sector with a high prestige but also highly commercialised and integrated within the cultural industries the inputs and spillover effects deriving from artistic activity, which are recognised by other authors as driving forces of creative clusters (Scot, 2004; Evans, 2009) and innovative *milieus* (Hall, 2000; Landry, 2000).

Looking at the arts from a different perspective, David Throsby (2001) suggests a concentric model of the cultural industries composed by: core creative arts (literature, music, performing arts, visual arts), other core cultural industries (film, museums and libraries), wider cultural industries (heritage services, publishing, sound recording, television and radio, video and computer games) and related industries (advertising, architecture, design, fashion). According to Throsby, cultural industries are defined as activities that involve some form of creativity in their production, are concerned with the generation and communication of symbolic meaning and their output embodies, at least potentially, some form of intellectual property (Throsby, 2001). This definition has the merit of providing a clear set of criteria in defining the cultural industries, but problems may arise while de-

termining whether, and to what extent, individual activities are to be considered cultural industries.

One by now 'classical' definition of cultural industries that takes into account the intertwining of industrial with cultural production comes by Towse. According to Towse, cultural industries actually 'mass-produce goods and services with sufficient artistic content to be considered creatively and culturally significant. The essential features are industrial-scale production combined with cultural content (Towse, 2003). Towse makes another clear distinction between 'creative arts' and 'cultural industries'. The difference according to Towse is a difference of scale and it can be considered as the key for the definition of industrial versus non-industrial production: cultural industries employ industrial scale methods of production, creative arts don't. This sheer difference of scale was also pointed out by Williams, who distinguished between the corporate ownership methods of production associated with the development of mass reproductive technologies, and the survival of older artisanal methods of production (Williams, 1981).

UNESCO (2009), following its seminal approach to cultural industries, defines them as 'those industries that combine the creation, production and commercialisation of contents which are intangible and cultural in nature. These contents are typically protected by copyright and they can take the form of goods or services'. Other international agencies, such as International Labour Organisation (ILO), International Trade Centre (ITC), World Intellectual Property Organization (WIPO), have adopted more or less similar and converging definitions on cultural industries for their programs and initiatives.

Another problematic node for classification schemes (a part for the position of the arts) is the concept of creativity and its relationships with culture. 'Creative industries' are considered by Flew (2002) as an extension of the term 'cultural industries' that has created definitional problems so that it has become increasingly difficult to recognise the distinctive nature of the sector and thus to determine its 'exact boundaries' (see also Galloway and Dunlop, 2007; Hesmondhalgh and Pratt, 2005).

Creativity is defined in many ways, proving the complex multidisciplinary nature of the concept. According to Boden (2003), it is 'the ability to come up with ideas and artefacts that are new, surprising and valuable'. The Cox Review of Creativity in Business defines it as 'the generation of new ideas – either new ways of looking at existing problems, or of seeing new opportunities, perhaps by exploiting emerging technologies or changes in markets' (HMT, 2005). Florida (2002) suggests that 'creative work is often downright subversive, since it disrupts existing patterns of thought and life'.

It has been widely argued that any industry is potentially creative (Howkins, 2001; Pratt, 2011a; Hesmondhalgh and Pratt, 2005). Galloway and Dunlop (2007) warn about the fact that mixing cultural creativity with all other forms of creativity fails to take adequate account of important differences between cultural and creative industries.

Howkins (2001) suggests that the term 'creative industry' should apply in all the cases where 'brain power is preponderant and where the outcome is intellectual property'. The same argument is taken up by Towse (2003), who considers the copyright concept as too wide-ranging, and criticises its usage as a determinant for defining the cultural industries. On this basis, there are no reasons why definitions such as the one by the previously mentioned DCMS mapping document and others similar to it, should not include other sectors such as science or business.

It seems that confusion over terminology is bound to continue, as conflict persists between the two different viewpoints: the one which sees cultural production as just one type of creativity, and the other that considers culture and cultural products as something distinctive. Different labelling exercises, enacted for the purpose of uttering a sense of order in a sector that is strongly marked by large overlapping areas between the cultural and creative domains, have forced the problem of classification beyond the breaking point.

Indeed, subcategories that more often recur in classification schemes are highly inhomogeneous and the same distinctive characteristics may apply to different groups of industries; this leaves room for ambiguities. To clarify the concept: industries such as advertising, architecture, design, software, film, TV, music publishing, performing arts are strongly dependent to the *nature of* labour inputs, that is 'creative individuals'; industries such as commercial art, creative arts, film and video, music, publishing, recorded media, software, are 'copyright driven', their performance relates to the nature of asset and industry output, digital content industries such as the commercial art, film and video, photography, electronic games, recorded media, sound recording, information storage and retrieval, rely on the technology applied to the production process; cultural industries such as museums and galleries, arts education, broadcasting and film, music and performing arts, literature, are often related to *public policy* function and funding. Defining criteria for classification of creative industries when dealing with such a complex organizational character, it is not an easy path to undertake. Furthermore, definition criteria are often subject to specific political and policy requirements.

In an attempt to capture the complexity of the subject and to provide a comprehensive definition of creative industries, UNCTAD (2008) proposes a 'large sleeve' scheme, that includes also manufacturing and service industries: 'creative industries are cycles of creation, production and distribution of goods and services that use creativity and intellectual capital as primary inputs; constitute a set of knowledge-based activities, focused on but not limited to arts, potentially generating revenues from trade and intellectual property rights; comprise tangible products and intangible intellectual or artistic services with creative content, economic value and market objectives; are at the cross-road among the artisan, services and industrial sectors; and constitute a new dynamic sector in world trade'. This classification has the advantage of being less restrictive because it encompasses both cultural and technological dimensions of creative industry. On the other hand, problems may arise when it comes up to mapping such a manifold definition. One question would be how 'sharply' the sector boundaries can be identified, in the presence of activities that are not intrinsically creative. The other concern is about the difficulty of providing homogeneously detailed statistical cover to all the subcategories.

These issues are addressed in detail in mapping documents that have proliferated in recent years. Reports analyse the state of the art of creative industries definitions, argue their own choices, and suggest a 'newer' classification. The lack of a common framework for classification brings about the inclusion or exclusion of entire groups of activities from classification schemes, returning in highly diversified measures of the economic weight of the creative sector. To illustrate this, in Figure 1.1 we have schematised the different weights that groups of economic activities (associations of SIC/NACE codes) might reach, as a function of the combination between the categories type (arts – cultural industries – creative industries) and their respective position in the value chain (creation – production – distribution). The further we move from the 'core cultural' categories and from the sphere of creation, the larger and undefined the codes associations become. Including or excluding these categories from the classification scheme involves the introduction of macroscopic differences with respect to other classifications.

CHAPTER 2

Understanding creative industries

2.1 Key features of cultural goods

The invention of printing, in 1452, radically changed the dynamics of cultural production and consumption. In this context it is of paramount importance to note that the explosive development of the print media followed the golden rule of the free market press; the cheaper the copy, the more the potential profit. Every new technological improvement of the printing press reduced the time and effort for the reproduction (Briggs and Burke, 2005). This paved the way for the establishment and consolidation of a wide range of newspapers, political, religious and civic organizations.

The new print media were market-oriented. The more viable they became, the more they grew. The more they grew, the more complex became the range of civic institutions living in symbiosis with them – salons, humanistic societies, private charitable societies, religious groups and their affiliated press, political newspapers, scientific communities and the like. These developments are certainly associated with the birth of the modern democratic state. It can be easily argued that the mass media (print media at that time, social media in the present time) became the incubator, the basic infrastructure, the carrier of the new 'public sphere'. Habermas – a pupil of Adorno – contended that the public sphere was located somewhere between the State and the individual, and its vehicle was 'public opinion', which since then became responsible for the legitimation or contestation of all political, social or economic power (Habermas, 1989). The growing reproduction capacities of modern technology are often considered responsible for the so-called 'industrialization of culture', even though commodification of cultural products goes back to ancient history. As it is often the case in our modern world, also in the ancient world unique artistic products associated with symbolic and even sacred meaning, were nonetheless put for sale or exchanged for other objects. Here the production of coins in the ancient world or the early Chinese production of porcelain is brought as a typical example of increasing productivity via labour division (O'Connor, 2007).

Theodor Adorno was the first to point at the significance of the method of production in cultural industry when it comes to distinguishing between traditional or 'pre-industrial' means of production, and 'industrial' means of production of cultural industries (Garnham, 1990). Today's cultural industries are characterized by a more complex intertwining of industrial-scale production methods and symbolic meanings (Hesmondhalgh, 2002). Yet, Adorno's dualistic viewpoint transposed to a different, more complex, virtual and post-industrial context, remains distinguishable in the antagonism between the so-called 'classic' cultural industries (broadcasting, film, publishing and musical records), and 'new' on-line social media (search engines, online platforms such as Youtube, or Facebook) also with a high level of specific branding and symbolic meaning.

In the early 20th century audio and video were first stored 'physically', now they are stored digitally and shared virtually with the entire globe. The cost for storing and sharing continues to fall, in what seems to be at first sight a total democratic push forward through the commons of information technology. Storage and reproduction are a central theme with regard to the commodification of art and of cultural products. The core of a cultural commodity contains an inherent tension between its use value and its exchange value. Cultural commodities are always cheaper to reproduce; yet the cost for *producing* them is always on the rise. Again, the more copies are sold, the greater is the return on the investment that includes the growing cost for the production of the original 'concept'. What we now witness is the collapse of the 'conceptualization' of a cultural product in its 'marketization' – the more they are harmonized, the less they differ. In a perfect vicious circle, marketization defines the cultural product before the latter is conceived, produced and reproduced as such. Caves (2000) maintains that the management of the marketization of cultural products is just another difficult business cycle management issue, whilst Ryan (1992) argues that there is a fundamental contradiction in it. Regardless of the side one might take in this debate, it is clear that the level of unpredictability in consumer's behaviour towards cultural products is high, as the prediction and

'pre-programming' of the consumer's taste in the products proposed by the cultural industry is not possible (Peterson, 1990). Thus, the need for new, highly marketable cultural products is always intertwined with high demand unpredictability.

Another important question related to the cultural products is the computation of their exchange value. Miege (1989) proposes three archetypical modes for realizing exchange value. The first mode is the sale of physical objects that were seen as carriers of cultural content. These objects (books, videos, CDs) are sold to individuals. The second mode is the TV/radio broadcasting generally free of charge or available to subscribers (mostly for TV channels). In such cases money was made through ads or by sponsorship, or even by taxation money in the case of public broadcasters. In this second mode of realising exchange value of cultural products, newspaper stay somewhere in the middle with part of the earnings made by direct sales, but with most of the income realized by selling advertisement. In present days cultural demand is stimulated by the hyper-reproducibility of digital products. One of the most controversial effects of this drift is the free access to cultural contents made available through cooperative exchanges (creative commons licenses or «copy-lefts», p2p exchange protocols for mp3 and mp4 files and the circulation of free software) or social networking (Facebook, MySpace, Twitter). Specialized streaming platforms such as Spotify or Netflix make available enormous quantities of digital music and films on pay-per-access basis. Their approach is in some aspects similar to the hackers' job – being able to gain and give access to digital content stored in the Web –, with the difference that for that access these platforms charge symbolic prices that little have to do with the value chains of cultural products. The market of music and films is now dominated by one, unique, commodity generated by the digital revolution: the whole of music and the whole of films. Distribution of cultural content at ridiculous prices or for free, is making a genocide of authors, talents, art professions (Baricco, 2018). The work of musicians, writers, journalists, wanders in the digital space producing profits that do not return to authors. Those who make money are those who distribute rather than those who create cultural contents. The third mode for realizing exchange value according to Miege (1989) relates to public performances (as cultural products) – theatre performances, concerts and cinema, which are offered to a limited number of direct viewers whom are charged the ticket price. Taking these three modes into account we see that the different specialized subsectors realize exchange value in their specific ways and manage demand and creative labour through differing modalities and levels of capital investment and administration arrangements.

Creative labour is the other bone of content in the cultural industries. The post-modern 'enslavement' of the artist into the 'art factory' was taken up by Adorno, who predicted that any artist who wanted to remain free could do so only to starve. On the other side, Williams (1981) argued that the 'free artist' would not disappear under the conditions of mass production of cultural products. Williams accounted historically on the status of the artist as he moved away from patronage into a freelance market agent, starting his historical consideration with a post-artisanal phase, in which artists relied on intermediaries for distributing their products in the free market. As the intermediaries gradually invested more and more in the purchase of cultural products for the purpose of selling them at a profit, they controlled more and more the market, and their position vis-à-vis artists was growingly superior. At some point they could freely dictate to the artist the market demand and thus effectively influence (if not totally dictate) the supply. Finally, the intermediary, and not the artist, had direct relations with the market. The next stage of the status of artist was set in the 19th century, in which the artist was more of a market professional, that is, more of a freelance, involved directly in the marketing of his own products. By the active management of copyright and royalties the artist was able to receive a direct share from the exchange value of his merchandise. Williams set the final development stage of the status of artist in the 20th century, where the artist is transformed into 'a creative' – a corporate professional, employed full-time by corporate cultural producer. This phenomenon is seen very clearly in the 'new media' - cinema, TV, radio channels, online blogs, and so on, requiring high levels of capital investment in infrastructure, operations and technology.

To the definition of cultural industries the concept of joint goods is pivotal. Certain industries may produce certain cultural goods, yet in addition to, or as a complement to non-cultural goods. In sheer quantitative (financial) terms, the share of the cultural goods to the company's turnover might be considerable inferior to the share of the non-cultural goods. It is clear that the proportion of cultural versus non-cultural goods in this case is immeasurably bigger than in the creative arts sector. Martin (2004) claims that it is possible to clearly define whether a certain product is functional or cultural. Yet, this difference at times is hard to make. Architecture may be invoked here as an example: it is both functional and cultural. Facades and interiors of public and private buildings are more often than not clear cultural statements. In this case it would be up to us to decide to what extent this 'architectural product' is cultural versus functional. This, to a certain extent, brings us back to the discussion about the symbolic meaning and the use value considered as a benchmark between the cultural and creative domains, and the consequent distinction that it is often made in classification schemes between economic activities having as 'first use' the communication of ideas, such as books, films, theatrical plays or music, and activities that have a primary functional value, such as fashion design, advertising and architecture.

Whilst methods of production and commodification cannot ultimately define the meaning of what culture is, they are keys to understand why and how these industries should be addressed both by economic and cultural policies.

2.2 The impact of digital revolution

The digital revolution is not only an expression of the inexorable technological advancement, it also represents the unease of new generations towards the twentieth century civilization (Baricco, 2018). Since the 1970s, and intensively since the turn of the new millennium, digital technology has radically transformed society through a series of actions bearing remarkable symbolic value. This transformation is taking place in absence of any specific ideology and far from the palaces of power, thanks to technological tools, available to everyone and able to blow up mediations. More than redistributing power, the digital revolution has spread around countless possibilities of action, ending up by creating a new elite (Brown and Czerniewicz, 2010), very different from traditional 20th century elites, able to move effectively in the digital space, steering models, imposing tastes, establishing rules and accumulating enormous wealth. This revolution, still in full swing, to which it does not yet correspond any model of economic development and social justice, has enhanced existing gaps and asymmetrical distribution of wealth.

The digital revolution also represents a shift in perspective towards knowledge, now easily accessible but perhaps more superficial. Anyone in possession of a device with internet connection can access unimaginable quantities of information stored in digital format from any part of the globe. Google, Amazon, eBay, Spotify, make available to users digital worlds whose edges are finite but unreachable. The Whole (all the music, all the books, all the films, etc.) is no longer a hypothetical quantity, it has become a feasible and reasonable quantity of measure. This has strongly modified the way in which people experience culture. Prior to the digital revolution cultural experience was concentrated, limited to one single aspect and very personal, while in present days it resembles more to a continuous movement in the digital space, that only stands still for the time necessary to regain propulsion needed to move to the next interconnected node (Alicante, 2011).

There is impetuous discussion on the growing monopolistic power of web giants and its effects on culture, widely arguing how they are limiting creativity, autonomy, and earnings of artists, writers, and intellectuals, thus diminishing the power of culture (Tufecki, 2017; Cohen, 2017; Timberg, 2015; Tapling, 2017; Foer, 2017). As a matter of fact, the power of the dominant companies is in their design to retain users' attention, especially on the mobile Web. In this context, their position is more asymmetric than that of older media. Joseph Stiglitz (2012) has warned that this imbalance is distorting financial markets and endangering innovation. In absence of competitors the largest tech companies are abusing their dominance to promote their own services showing clear interests in expanding their involvement into other areas of their customers' lives. Data, news, ideas, are in the hands of a few players which, as sadly demonstrated by recent events, in different occasions have provided autocrats with technological tools that can be used to exploit people's choices and opinions in order to advance political and commercial agendas. This asymmetry compounds a big challenge to democracy (Tenner, 2018).

Despite strident problems and the obvious flaws into the system, the irreversible process of society's digital transformation is generally well accepted by masses because it is considered to be responsible of an improvement in peoples' lives. With the advent of smartphones and the multiplication of Apps covering countless needs and desires, our daily experience with the digital world increasingly resembles to videogames. World loves Apps: 197 million Apps were downloaded in 2017, while a simple but effective messaging system born in 2009 called WhatsApp, is nowadays used by 1 billion people.

Direct democracy, the one that blows up mediations leading people to intervene directly in political action, has become true in a world where the most widespread Encyclopedia is written by everyone and the news come through our Facebook feeds. In 2009, for the first time the digital insurrection generated a new political party, the Italian Movimento 5 Stelle (M5S), whose representatives are interactively chosen by people subscribing an online platform named Russeau. In ten years, the M5S has become the first political party in Italy, but Russeau still remains an isolated case, anticipated perhaps by MyBo, the social network designed in 2008 by one of Facebook's co-founders to boost President Obama's electoral campaign.

Sharing economy platforms like Airbnb and Uber, born in 2009 from the will to skip mediations, include a concept of shared ownership as well, which finds recurring applications in examples of cohousing, carsharing or crowdfunding, and which certainly does not please the castes that control collective consumptions (Frenken and Schor, 2017). In 2011 Apple launched iCloud and, since then, we all had the opportunity to dematerialize reality. Our data are now in clouds, that is, nowhere, they follow us without taking up space or time. While this «dematerialising» process appears perfectly coherent with the «immaterial» nature of cultural goods, professed long before the digital revolution (Hirsch, 1972; Lacroix and Tremblay, 1997), their material nature remains still unquestionable (Miller, 1987; Storey, 1999; Lévy, 2007).

There is perhaps a logical continuity between the world of culture and the digital world. Probably both are the result of the same inspiration: creating different, more exciting, versions of the world. As a matter of fact, videogames, as well as theater, paintings, films, are versions of the world expressed in different languages invented by man. From the point of view of a millennial, fruition of "traditional" art and culture today would probably be expensive and boring: slow, difficult to access, un-communicative, un-interactive, un-portable, un-shareable. The conversion of what we might term a "classic" cultural product (the book, record, film or videotape) into a digital format and its fruition through mobile electronic devices, quite similarly to other entertainment opportunities such as the videogames, offer indiscriminate, ubiquitous, portable, desecrated enjoyment, independent of moments of time, places, rituals and specialised intermediaries. We could then think of the inexorable end of artists, creatives, intellectuals, blatantly not compatible with the digital revolution, since the digital age has generated millions of potential content creators. Is there still room in the digital age for the most exclusive and arrogant amongst the 20th century elites? In fact, the creativity of individuals continues to have its weight, although the world of culture has become less exclusive and more unrespectful; anyone can insult artists and intellectuals online, but web still seems to need them.

Cultural industries: music, advertising, cinema and TV, exhibitions, are anything but dead, and are adapting themselves to the digital age by developing "border areas" such as eBooks, Netflix, streaming of classical concerts or theatrical performances on Spotify, virtual museums. The new ways of consuming culture do not seem to have (yet) sunk the traditional ones. eBooks have not eliminated paper books, live concerts are still held, exhibitions are full of spectators and cinemas have not disappeared. The digital revolution has succeeded in what years of cultural policies in many Western countries had failed: bringing culture closer to the masses. The result is the opening doors of theaters, museums and libraries to younger people.

Some branches of culture are evolving faster than others to be compatible with the digital revolution. The explosion of digital social media is a direct challenge to the methods of today's cultural production. In all cases, by influencing the media the digital revolution has radically changed the landscape of communication, and ultimately society itself. Taking into account their particular role in influencing public perception and in directly or indirectly shaping public opinion through their capacities to articulate the very self-representation of society, to reproduce and change its hallmarks and symbols, cultural and creative industries are thus located at the very centre of the vortex of modern (and post-modern) history.

2.3 The economic context of creative industries

Creative economy is clearly linked to the process of metropolization, to the knowledge economy and their economic background. The semantic profusion that characterizes research on these topics might show some confusion: the knowledge economy promotes learning regions/cities (Florida, 1995; Storper, 1997; Glaeser, 1999), intelligent cities (Komninos, 2002), innovative milieus (Aydalot, 1986; Camagni, 1995), creative cities (Landry, 2000; Cohendet et al., 2010), nursery cities (Duranton and Puga, 2001), knowledge cities (Ovalle et al., 2004; Yigitcanlar et al., 2007), urban clusters (Gaschet and Lacour, 2007). Theoretical proposals share a common set of inspirations; yet, they remain heterogeneous and sometimes contradictory. Research traces that more clearly emerge relate to economic geography and the inclusion of dynamic externalities in the process of urban growth, the economy of knowledge and its deployment to the concept of 'knowledge city', the concept of creativity and creative clusters (Gaschet, Lacour and Puissant, 2011).

The acknowledgment of the active role of cities in the process of economic growth was renewed since the work of Romer (1986) and Lucas (1988) on knowledge spillovers and, later on, with the Krugman's core-periphery model that launched the new economic geography (Krugman, 1991). These influential contributions, highlighting the geographically localized character of interactions, have stimulated the economic analysis of spatial issues, integrating economic geography with mainstream economics and the more traditional research in urban and regional economics (Fujita and Krugman, 1995, Fujita, Krugman and Venables, 1999; Fujita, Krugman and Mori, 1999). Several studies have shown the superiority of dense and diversified urban environments that have a higher capacity to innovate (Henderson et al., 1995; Audretsch, 2002; Feldman, 1996; Duranton and Puga, 2001; Boshma and Iammarino, 2009). Cities are not only places that benefit from the presence of infrastructure and of specialized and diversified suppliers; they are also the places where benefits associated with urban concentration are produced over time and endogenously.

The rich debate on these issues has reanimated the opposition between localization and urbanization economies, transposing it in terms of opposition between Marshall-Arrow-Romer-type of dynamic externalities, which refer to technological spillovers between firms in the same industry, and externalities theorized by Jacobs (1969) which consider industrial externalities related to the diversity as the main source of innovation and growth (Peri, 1998; Henderson et al., 1995; Black and Henderson, 1999; Glaeser and Maré, 2001; Rosenthal and Strange, 2008). Recently, a new stream of research presents a more nuanced view of the benefits brought by 'specialisation' and 'diversity'. Proponents of the 'related variety' concept have argued that beneficial externalities are more important in geographical areas where diverse sectors are able to develop intense relationships. Variety is indeed a source of competitive advantage for the firms located in a place, but only if the diverse sectors that are located together have complementary capabilities and resources. In these cases, 'knowledge spillovers' take place around a 'theme', rather than around a sector (Asheim et al., 2007; Cooke, 2007; Boschma and Iammarino, 2007).

Other studies focus more specifically on the relationships between the metropolization and the 'knowledge economy'. This term identifies emerging industries and activities that differ from the traditional sectors for a systematic and extensive use of knowledge. Many activities within high-technology manufacturing, business and financial services and creative industries, fit this description (Lash and Urry, 1994; Scott, 2001a; Healy, 2002a). The rise of 'knowledge-intensive services', often cited as the main metropolization force (Duranton and Puga, 2005), is not the only component of the process of structural change affecting the transition to the knowledge economy of metropolitan areas; Van Winden et al. (2007) define knowledge city trough the interaction between the knowledge base and other components of urban space (industrial structure, urban amenities, accessibility). Wood (2006) also stresses the notion of the spatial reorganization of metropolitan economies under the impulse of knowledge-intensive services.

The process of metropolization is as well influenced by the so-called 'advanced producer services' providing intermediation between production and consumption (Marshall and Wood, 1995) and centred around the financial sector, which are considered by Sassen (2001) as a distinctive characteristic of global cities. Creative activities such as design and advertising or media and new media are identified in literature as advanced producer services (Beaverstock et al. 1999; Krätke, 2003; Krätke and Taylor, 2004).

Pratt (2011a) underlines the fact that creative industries in general might be considered as advanced producer services when they are in the conditions of acting as nodes within international production systems.

According to Florida (2002, 2004), creativity has become the key competence in the knowledge economy, giving rise to the emergence of a distinct 'creative class'. The presence of creative people has become the driving force of local economic development, promoting innovation and production of knowledge. The capacity of cities to attract creative individuals in their choice of residential location fosters the location of knowledge-intensive activities and job creation. Florida's controversial thesis on the rise of the 'creative class' and its role in regional development has undergone increasing popularity in North America and in Europe, as witnessed by different national and international initiatives (Asheim, 2009; Andersen and Lorenzen, 2007; Chantelot, 2006; 2009). This approach introduces alternative measures of human capital such as tolerance, bohemian index or gay index, much discussed and criticized (Peck, 2005; Montgomery, 2005; Nathan, 2007; Glaeser, 2005; Markusen, 2006; Donegan et al., 2008). Storper and Scott (2009) disapprove the excessive focus on residential amenities as the foundation of the metropolitan dynamics and point out the theoretical weaknesses of this approach who neglect the essential, structural contribution of productive logics as well as institutional forms by which the concentration of human capital can generate creative innovation dynamics and collective knowledge (Landry, 2000; Rosenthal and Strange, 2004). The debate has fueled further research focusing on the role of creative professions, the processes and the determinants for creative clustering and their impacts (Markusen and King, 2003; Florida, 2002, 2004; Lee et al., 2004; Markusen, 2006; Scott, 2006; 2010; Lacour and Puissant, 2007; Asheim and Hansen, 2009; Lazzeretti et al., 2012).

2.4 The spatial context of creative industries

The specific role of the city and the connections between the cultural significance of places and their economic performance constitute a fertile research stream. There has been increasing emphasis on the 'atmosphere' (Marshall, 1890), the buzz, the scene, the *genius loci*, which make up a 'creative *milieu*' (Hall, 1998; 2000). Charles Landry has drawn attention to the significance of a *creative milieux* to the development of creativity in modern cities and regions, which he defined as a combination of *hard infrastructure*, or the network of buildings and institutions that constitute a city or a region, and *soft infrastructure*, defined as 'the system of associative

structures and social networks, connections and human interactions, that underpins and encourages the flow of ideas between individuals and institutions' (Landry, 2000).

To exist, creative *milieux* necessitate the support of facilities, institutions, embedded knowledge and practices; thus, they are rooted in dense urban environments. Scott (2004) associates what he calls 'cultural commodity production' to cities, which are defined as '*collectivities of human activity and interest that continually create streams of public goods that sustain the workings of the creative field*' (Scott, 2001b). Cultural production and consumption transform the city through its '*shopping malls, restaurants and cafés, clubs, theatres, galleries, boutiques*' (ibid.).

There is a direct link between creative milieu and urban quality, witnessed by high urban real estate values. The so-called 'independents' – micro businesses and freelancers on the cultural and creative sectors – have proven to be active players in the process of gentrification and the construction of the cultural identity of urban neighbourhoods where they reside (O'Connor and Wynne 1998). Cultural hot spots such as art galleries, concert halls or museums, as well as spatial concentrations of small-scale cultural and creative activities are increasingly becoming a key element of culture-led urban regeneration strategies, much in vogue amongst city governments. This process is fostered by the optimism shown by many authors over the last decades, about the role of cultural and creative economy for job creation and urban regeneration (Bianchini, 1993; Landry, 2000; Throsby, 2001; Scott, 2001b; 2004; 2006; 2010).

The structural characteristics of creative industries have an evident impact on their spatial structure. In a context of achieving its largest spatial extension, thanks to the existence of organizational networks across the globe held by multinational corporations which are expanding into all the segments of new cultural economy, and the opportunity of transmitting both explicit and tacit knowledge over the globe, thanks to the new communications technologies, creative production appears even more polycentric and geographically differentiated (Scott, 2010). Global and local cultural networks are defined by Grabher (2001; 2004) as 'heterarchies', self-regulating and learning systems that allow for future-orientated 'adaptability'.

It has been widely argued that creative industries are faced with a difficult business model; in this context, local networks help actors to manage the inherent riskiness of their business (Banks et al., 2000; Bilton, 2007). Spatial proximity of small and medium enterprises networks produces economic benefits such as common knowledge or specialized and flexible human resources; a pool of 'untraded externalities' within each local network (Porter, 1998a; 1998b; Cooke and Morgan, 1998; Gordon and McCann, 2000; Martin and Sunley, 2003), complemented by shared knowledge rooted in cultural identity. These offer to local companies operating in the creative sector a competitive advantage because the (mostly tacit) knowledge produced and exploited locally would not be easily transferred or replicated elsewhere (Bathelt, et al. 2004). O'Connor (2004), argues that tacit knowledge – as opposed to codified knowledge – is tied to place, and cultural industries heavily rely on learning-by-doing practices and on skills diffused through specific related networks.

Although creative clusters as a form of economic organization are weakly theorized if compared to industrial clusters (Darchen and Tremblay, 2014), an increasing number of studies on creative places operate a 'creative cluster' approach. These studies examine the processes by which creative clusters generate externalities and the relationships with the urban milieu where they are located. Lorenzen et al. (2008) explain how the new cultural economy is characterized by a tendency to agglomerate in specific places where inter-sector knowledge spillovers are likely to occur. Lazzerati et al. (2008) analyses creative Local Production Systems in Spain and Italy, showing their urban nature and their tendency to cluster. De Propris et al. (2009) demonstrate that creative industries tend to locate near each other depending on their technological complementarities. Urban creative clusters involve complex divisions of labour, driven also by new ICT developments, and they are characterised by the preponderance of small, often micro-businesses, and freelancers (O'Brien and Feist, 1997; Pratt. 1997; Creigh-Tyte, 2001).

Other case studies have closely looked to the structure of creative clusters, demonstrating that different sub-sectors of creative industries, such as music, visual arts, film, fashion, media, crafts, and so on, are highly networked at the local level and that they operate as clusters (Pratt 2000; 2002; 2004a; 2004b; 2004c; Kebir and Crevoisier, 2008; Turok, 2003; Wenting, 2008; Kratke, 2002; Bathel, 2002; Tremblay and Rousseau, 2006).

As Scott (2010) argues, place, as a container of knowledge, traditions, memories, and images, is an important ingredient in the creative mix of inter-firm networks and local labour market relationships. Creative clusters, embedded in residential neighbourhoods, support processes of urban regeneration and contribute to creating employment. Understanding the mechanisms through which creative industries contribute to the economic performance of cities, but also its relations with the urban structure, represent an important challenge.

CHAPTER 3

Culture programmes and policies

Several international and national studies point at the system of cultural and creative production as one of the most dynamic sectors of the economy in developed countries. The KEA³ report on the economy of culture in Europe (KEA, 2006) confirms that the weight of the cultural and creative sectors within the feeble European economy registered a steady growth, yielding a positive impact on employment. The picture of the sector emerging from the data boasts a turnover of about 654 billion Euro, equal to 2.6% of the European GDP, a comparative growth of 12.3% with reference to the European economy as a whole, and an overall employment share of 3.1%.

The trend has been positive ever since. Four years later, the European Competitiveness Report (European Commission, 2010) established that, in the midst of a fully-fledged global economic crisis, the cultural and creative sectors in the EU accounted for 3.3% of GDP providing direct employment for 6.7 million people (3% of total employment). In the last years, even though there are conflicting accounts on the sectorial data, the creative and cultural industry managed to uphold a higher growth-to-GDP ratio if compared to the remaining sectors of the EU economy.

A communication by European Commission to the European Parliament entitled 'Promoting cultural and creative sectors for the growth and jobs in the EU' (2012), citing Eurostat EU-LFS, notes '... *between 2008 and*

³ KEA is Europe's leading consultancy and research center on culture and creative industries.

2011, employment in the cultural and creative sectors proved more resilient than in the EU economy as a whole with growth rates varying however between sub-sectors. This tendency is all the more interesting because some sectors have a higher percentage of youth employment than the rest of the economy'. The communication defines the creative sector as 'a largely untapped resource' for future EU strategies.

Figures matter when looking at the fashion industry (including design, manufacturing of fashion materials and goods, and their distribution) and high-end industries (covering in particular high-end fashion, jewellery and watches, accessories, leather goods, perfumes and cosmetics, furniture and household appliances, cars, boats, as well as gastronomy, hotels and leisure), which rely on a strong creative input. They account for 3% of the EU GDP each and employ respectively 5 and 1 million people, with employment in the high-end industries expected to reach 2 million by 2020 (Idea Consult, 2012; Frontier Economics, 2012).

There is agreement on the fact that in developed countries creative industry is in a strategic position to trigger positive spill-overs in other industries, in particular in high-end industries and on innovation in general, by contending the importance of culture and creativity as a key underlying aspect in the value chain of an increasing number of sectors of economy. In other words, culture and creativity boost the added value of the economy. The increasing weight of design in the manufacturing industries is brought as an example to prove the point, through the markedly positive correlation between investment in creativity and innovation (Oakley et al., 2008).

These features perhaps help to better account for the recent shift towards creativity discussed in the previous sections, as well as the efforts in building up policies and programmes, which, from the year 2001 onwards, have resulted in a large number of documents on culture and creative industries.

3.1 Promotion of the cultural and creative sectors

The UNESCO Universal Declaration on cultural diversity, adopted in 2001 by the UNESCO General Conference, represents the key reference policy document for promoting the cultural and creative sectors worldwide. It focuses on the preservation of cultural diversity as a necessary element for humankind (UNESCO, 2001). Along with the Declaration, an Action Plan for its implementation was issued, providing guidelines for the development of public policies in the field of culture. The main lines of the Action Plan include, amongst others, the preservation of cultural heritage, the strengthening of cultural industries in all the countries, the recognition of the rights of authors and artists.

The Agenda 21 for Culture (2004) is the EU reference policy document on culture for cities and local governments. Based on the UNESCO Declaration, it develops detailed priorities for local cultural policies by addressing governance, sustainability, social inclusion and economy. Decentralization of cultural policies and intergovernmental coordination cultural indicators are considered key issues to be addressed by local governments. In analogy to the UNESCO Declaration, cultural heritage, cultural industries, access to the digital dimension of culture, rights of authors and artists are listed amongst the Agenda 21 for Culture priorities. This document considers cultural promotion "*as a catalyst for creativity and innovation in the context of the Lisbon Strategy for jobs and growth*". To be noted here the direct link between culture and economic growth.

The first comprehensive cultural policy at the European level is The European Agenda for Culture in a globalising world – issued by the European Commission in 2007. It lists amongst its general objectives the promotion of cultural diversity and intercultural dialogue, the promotion of culture as a catalyst for creativity and as a vital element in the EU's international relations (European Commission, 2007). The Agenda was followed by the publication in 2010 of the 'Green Paper, unlocking the potential of cultural and creative industries' whose aim was '... to spark a debate on the requirements of a truly stimulating creative environment for the EU's Cultural and Creative Industries...'. This document identifies priorities for cultural policies, such as: cultural diversity; the digital shift; new spaces for experimentation, innovation and entrepreneurship; new skills; access to funding; and mobility of cultural workers (European Commission, 2010). The disjointed term 'cultural and creative industries' appeared first in the document 'Green Paper, Unlocking the potential of cultural and creative industries' (European Commission, 2010). This policy document dismisses the previous conceptual organisation, considering the cultural sector as a whole. In so doing, it assimilates both the corporate and public sector into the 'new' conceptual definition of the 'cultural and creative industries'. As a result, predominantly public-funded branches of the cultural industries, such as theatres, museums and libraries and so on, are considered jointly to the private sector.

The latest cultural policy document is the New European Agenda for Culture, released in 2018. It underlines the importance of cultural and creative sectors for innovation, job creation, cohesion and well-being of societies. The vision of cultural and creative sectors within the EU is more and more focusing on an ecosystem approach to supporting artists, cultural and creative professionals and European content (European Commission, 2018).
The Work Plans for Culture 2011-2014, 2015-2018 and 2019-2022 are more pragmatic documents, citing cultural and creative sectors, creative economy and innovation as main priorities for cooperation in cultural policy making. These documents propose concrete guidelines and actions for achieving the priorities pointed out in the European Agenda for Culture and are based on the Europe 2020 Strategy, introducing key concepts of smart, sustainable and inclusive growth, obviously linked to knowledge and innovation. Cultural and creative industries, cultural heritage and culture statistics are listed amongst their priority areas. This policy agenda is complemented through a variety of actions and initiatives – such as the Creative Europe Programme – as well as funding from various Commission resources.

The European Capitals of Culture and the European Years are two additional policy formats that potentially impact the promotion of cultural and creative industries in European member states. The topic of the European Years changes annually. Depending on the topic, cultural industries and the initiatives related to them can be supported directly or indirectly. For example, the year 2009 was the European Year of Innovation and Creativity, that made a good opportunity for the promotion of cultural and creative industry projects. The year 2018 was the European year of Cultural Heritage, representing the commitment of European Commission to highlight the role of Europe's cultural heritage in fostering a shared sense of history and identity. More than 10.000 cultural events across the 28 participating countries were organized during the year, with the intent to raising awareness of heritage and history as a shared European resource and to encourage participation of different actors in cultural heritage projects. The initiative European Capitals of Culture, during the last 34 years, has promoted the richness and diversity of cultures in Europe, with the objective to increase the European citizens' sense of belonging to a common cultural area, and to foster the contribution of culture to the development of cities. This programme has enhanced the image of cities elected each year European Capital of Culture, contributing to boosting their tourism, activating urban regeneration actions and raising of their international profile.

These policies and strategies are closely linked to the funding mechanisms on the cultural and creative sectors. In times of crisis access to EU funds becomes more and more strategic. In this situation, EU funding for culture has undergone substantial transformations.

3.2 Funding programmes for sustaining culture policies

European programmes aimed at directly funding culture policies at the EU level are Creative Europe and Erasmus+. Cultural and creative industries can also rely upon different funding programmes, such as Horizon 2020, COSME, Connecting Europe facility and Cohesion Policy Funds. In addition, Commission initiatives and programmes in support of the culture sector include the European Social Fund, the European Globalisation Adjustment Fund, the European Regional Development Fund, the European Destinations of Excellence initiative and the programme ACPCultures+.

Creative Europe is by far the largest culture-specific funding mechanism of the EU. It particularly targets creative and cultural sectors with over 1.8 billion Euros for the time frame 2014-2020 in line with the Europe 2020 strategy (European Commission, 2010a). It intervenes directly on the economic dimension of culture, through loans and financing for the cultural sector. Creative Europe proposes to address several challenges related to 1) the lack of access to finance for European cultural projects 2) the fragmentation of the cultural space across the EU member states; 3) the digital revolution and 4) lack of available data on cultural/creative industries (European Commission, 2012a). The overarching objective of Creative Europe is '*To foster, to safeguard and to promote European cultural and linguistic diversity and to strengthen the competitiveness of the cultural and creative sectors with a view to promoting smart, sustainable and inclusive growth*' (ibid.). It proposes to do so by direct funding for the cultural sector, for the development of new audiences and for cross-border and transnational cooperation.

Erasmus+ is the EU's programme to support education, training, youth and sport in Europe. Its budget of 14.7 billion Euros will provide until 2020 opportunities for over 4 million Europeans to study, train, and gain experience abroad. Merging seven prior programmes, Erasmus+ offer funding opportunities for a wide variety of individuals and organisations, including universities, research, education and training providers, think-tanks and private businesses. Cultural and creative bodies are eligible for participation in partnerships, together with small and medium-sized enterprises, employers' associations, chambers of commerce, industry or craft. In particular, participation in partnerships of creative industries such as industrial and graphic design, software development, 3D publishing, is considered an advantage, since it supports the spread of a creative and innovative culture inside small businesses by transferring and implementing methodologies, tools and concepts that facilitate organisational development and product creation (European Commission, 2018).

Horizon 2020 is the biggest EU Research and Innovation programme,

with nearly 80 billion euro of funding available over 7 years (2014 to 2020) – in addition to the expected private investments that this investment will attract. It promises more breakthroughs, discoveries and world-firsts by taking great ideas from the lab to the market. The three strategic work directions of Horizon 2020 are competitive industries, excellence in science and better society. The common thread linking the three main goals is innovation (European Commission, 2011b). Cultural industries could make the difference in all three fields as far as research and development is concerned, even though their contribution in the 'excellence in science' may not be visible at first sight. In the work direction of competitive industries, they can promote job creation through research into 'creative jobs. The creative and cultural industries can create jobs themselves through small and medium-size companies that constitute a specific field of interest for Horizon 2020 with regard to the promotion of competitive industries.

The European programme for the Competitiveness of Enterprises and Small and Medium-sized Enterprises (COSME) aims to improving access to finance for SMEs in all phases of their lifecycle through specific financial instruments. COSME has a budget of over 1.4 billion euros used to fund financial instruments that facilitate access to loans and equity finance for SMEs. Financial instruments are complemented by resources from the European Fund for Strategic Investments (EFSI). Thanks to this budget, it estimated mobilisation of up to 35 billion euros in financing from financial intermediaries via leverage effects. The financial instruments are managed by the European Investment Fund (EIF) in cooperation with financial intermediaries in EU countries. As CCIs are in larger part classifiable as SMEs, access to funding through COSME programme is to be considered a plausible alternative.

The Connecting Europe Facility (CEF) is a key EU funding instrument to promote growth, jobs and competitiveness through targeted infrastructure investment at European level. It supports the development of high performing, sustainable and efficiently interconnected trans-European networks in the fields of transport, energy and digital services. In the current programming period Connecting Europe Facility (CEF) has a budget of 30.4 billion euros (€ 23.7 billion for Transport, € 4.7 billion for Energy, and € 0.5 billion for Telecom). CEF investments aim at filling the missing links in Europe's energy, transport and digital backbone. It is expected that the programme will involve creative industries operating in the fields of digital services and infrastructures.

3.3 Challenges to implementation of cultural policies

The juxtaposition of the political documents on culture and EU programmes providing funds for cultural and creative industries, points at several important conclusions.

European culture is more and more considered as a catalyst for economic innovation and creativity, export and internalisation of culture, new skills and new jobs. Funding culture is considered as a direct or as an indirect means to this end. Hence culture becomes a sort of excellent provider of 'added value' and a source of comparative advantage for European products. Documents such as the Green Paper are aimed at making the point to definitely prove the undisputable contribution of culture to the European economy. Creative Europe and Horizon 2020 are two examples of policy backed by consistent funding instruments. In order for the European institutions to gauge the impact of cultural policies on economy, the abovementioned policy documents such as Agenda 21, the European Agenda for Culture and the Work Plan for Culture urge for the development of new cultural statistics and indicators able to measure the effectiveness of programs in terms of economic output at the overall EU and at the regional cross-country level.

In the period 2007-2013 the EU allocated over 6 billion EUR on supporting regional cooperation among EU countries in the areas of culture, creativity or creative industries⁴. That accounted for 1.7% of the total budget, of which: € 3 billion were allocated for the protection and preservation of cultural heritage; € 2.2 billion were allocated for the development of cultural infrastructure, and; € 775 million were allocated to provide support for cultural services. Further support was provided to creative industries under other budget lines: research and innovation, promotion of SMEs, information society and human capital. Yet, beyond the glamour and the rhetoric, the importance of such support is easy to be overrated. The overall percentage of funding for purely culture-based projects in the EU structural funds is considerably inferior the percentage of funding for purely economy-based projects. It is arguable that such division puts culture markedly below its potential to contribute towards the achievement of the Union's Cohesion policy. Investments in culture per se (as detached by the creative industries), starting from 2007 were mostly related to the protection and/or promotion of cultural heritage, funding for infrastructure and services with a view of enhancing the touristic potentials of cultural heri-

⁴ Statistics by Infoview DG Regio database:

http://ec.europa.eu/regional_policy/projects/stories/index_en.cfm (accessed 24/11/2017).

tage sites. In terms of factual funding, culture-related projects may lag behind other types of projects supported by Structural Funds, such as creative industries. In the latter case, support through Structural Funds goes to research and innovation (networks, entrepreneurship, SMEs, clusters), information society (digitisation), education, urban requalification (in the framework of integrated projects), investment in human capital⁵, yet no data on the share these industries get through Structural Funds is really available. Very often cultural projects have to compete for their share in Structural Funds with infrastructure projects, such as construction of regional highways that link regions divided by national borders. In this situation, direct investment in culture is growingly challenged by a trend towards 'integration into other budget headings', as the following paragraph on the European Agenda for Culture – Policy Handbook may suggest:

'The challenge is how to further integrate the cultural and creative sectors into regional innovation strategies for smart specialisation, which in the current Commission proposals will be an ex ante conditionality to access funds. To this end, regions have to fully take into consideration the complex links between traditional cultural assets (cultural heritage, dynamic cultural institutions and services) and the development of creative businesses or tourism' (European Union, 2012).

Measuring inputs and impact of policy measures in the field of cultural/creative industries is a growingly difficult issue. Cultural policies are highly different in nature and in scope, ranging from the local, to the regional and to the global level. Defining and quantifying cultural/creative sectors and defining reference variables is very challenging, if we take into account the difficulty to measure such heterogeneous, interconnected and integrated with other sectors.

Official statistics cannot capture the full phenomenon of CCIs. Suffice to note that plenty of creative and cultural activities are run from outside of the 'official' functioning of businesses and companies, by non-permanent staff, freelancers, often on short-term, project basis. The digital revolution of the last decades has brought many creative sectors to converge and overlap, and new innovative forms of doing business, in particular

⁵ EU Member States and regions are invited to use Structural Funds to finance their own strategies in this field through investment priorities such as "promoting centres of competence; promoting clusters; developing ICT products and services; promoting entrepreneurship; developing new business models for SMEs in particular for internationalisation; improving the urban environment; developing business incubators; supporting the physical and economic regeneration of urban and rural areas and communities, etc.' – *Linking thematic objectives of the Commission Staff Working Document "Elements for a Common Strategic Framework" to culture and CCIs.*

creative-related business. These, in turn, are more and more difficult to be accounted for by traditional statistical sources. 'Core' activities accounting for the bulk of the creative industries sector – *advertising, design, communica-tion*, are characterized by the highly transversal nature. Very often these businesses are integrated into highly complex consulting firms that have little or nothing to do with downright cultural and creative industries. The approach based on classification schemes of economic activities according to their SIC/NACE code is subject to severe limitations. Yet, for many national and international institutions dealing with cultural statistics, this approach appears to be the only viable way for measuring the economic impact of the sector.

CHAPTER 4

From theory to practice: importance of the creative sector

4.1 State of the art mapping for the creative sector

The statistical challenge regarding cultural and creative industries is matched in its complexity by the sector-specific strategic challenge, as its limits are vague and vary according to the definitions and approaches used. Recent developments at European level have shown the willingness to produce reliable and comparable statistics, which would be able to assess the actual contribution of the sector to the economic and social development of Europe. Since 1997 Eurostat, the statistical office of the European Union has developed statistics on culture with the contribution of the Leadership Group on Culture (known as LEG).

The European Union approach on defining the cultural and creative sector has evolved during the years. The initial LEG classification on 'cultural' industries, based on 17 sub categories, was taken over by the KEA (2006) classification scheme, adopted for the purpose of measuring the economic weight of the cultural sector at European level. KEA classification builds on the following three conceptual layers to define the constitutive elements of the sector: arts; cultural industries; creative industries. The 'arts' gather a host of activities – the so-called Subsidized muse – that include: visual arts, performing arts, historical and artistic heritage, which are predominantly not oriented towards profit, except for relatively limited sub-domains. The 'cultural industries' refer to the industries of mass reproduction and distribution – as suggested by Adorno –, plus the

new media. They are organised in six categories: publishing, film, music, radio, television and video games. Cultural activities are complemented by production activities in which the cultural experience is a non-functional asset (no additional value with respect to the cultural fruition). The 'creative industries' include three sectors, in which the creative component is balanced by considerations of utility related to extra-cultural fruition, which include fashion, architecture and advertising. This classification scheme, inspired by the work of Australian cultural economist David Throsby (2001), reflects the historical phases of the development of the CCIs concept and, most importantly, accounts for the distinction between cultural productions that necessitate the 'visible hand' and those that are distributed through the market.

A further evolution in classification schemes was operated by ESSnet, a centre and network of excellence, created in 2009 under the aegis of Eurostat and funded by the European Commission with the assignment to improve the methodology and production of data on cultural sectors so as to meet the needs for better comparability at European level. The ES-Snet-Culture report, dated 2012, highlights the fact that there are various concepts of cultural industries and that the term of Cultural and Creative Industries (CCIs) is widely used in the EU-policy. Thus, extending the notion of the cultural industries to include specific creative sectors was seen as an expedient for remaining *'part of the international creative industries debate'* (ESSnet-Culture, 2012).

ESSnet-Culture has as primary objective the production of comparable data, therefore it suggests a 'minimal but solid and realistic approach based on common standards and existing classifications' based on the NACE classification codes for economic activities. The 'cultural and creative industries' (CCIs) include ten cultural domains (heritage, archives, libraries, books and press, visual arts, performing arts, audiovisual and multimedia, architecture, advertising, art and crafts) and six economic functions: creation, production and publishing, dissemination and trade, preservation, education, management and regulation. With this approach, software and ICT sectors are not included in the cultural and creative industries. Figure 4.1 illustrates the cultural domains identified by ESSnet-Culture, as compared to the previous LEG-Culture definition and the wider definition by UNESCO.

4.2 Classification schemes

The cultural and creative sector is by no means easy to map, considering its heterogeneous nature, its complexity and its elevated fragmentation. In

Figure 4.1 – Comparison of cultural domains covered by the European and UNESCO statistics frameworks (from ESSnet-Culture Final Report, 2012).

measuring the economic impact of the sector, national approaches often favour specific fields of cultural activities, on the basis of local cultural traditions or explicit policy needs. Suffice to note that the British approach, which advocates the economic concept of 'creative industries', places creativity at the heart of production processes and considers its products as intellectual property (and not only as copyrights). The French approach of 'cultural industries' is centred on the concept of 'content industry', which is based on mass reproduction and copyrights. The Scandinavian approach of 'culture and experience economy' is largely based on technological progress that facilitates the access and the distribution of cultural products (Santagata, 2009; Bille, 2012).

There is a clear dualism in Europe, distinguishing between countries that have developed functional strategies for the cultural and/or creative sector, such as the UK, France, The Netherlands, the Nordic countries, German-speaking countries, and the Mediterranean countries (Greece, Italy) as well as some former Socialist countries (Romania, Czech Republic) which focus their strategies on cultural heritage and cultural tourism, with cultural industries and creativity playing a subordinate role (Interarts and EFAH 2003).

By looking closely to the case of Italy, there certainly are historical and structural factors accounting for such approach. The country is deeply marked by the sheer weight of its heritage. It also has other important peculiarities, such as the fashion and style production, and a long-standing tradition of tourism. This, in turn, makes it difficult for Italy to align itself to Northern European schemes of cultural/creative sector policies, which are trending throughout the globe. However, something is changing in the direction of policy guidelines that are coherent with European Union vision for cultural and creative industries. A strategic achievement was the establishment of the Commission on Creativity and Cultural Production (*DM 30 November 2007*), which produced in 2007 the *White Book of Creativity*, focusing prevalently on quality of life and well-being, and which included amongst cultural and creative industries the industry of 'gusto'. However, this document did not find implementation into concrete cultural policy measures.

There are as well conceptual limitations preventing Italy from fully integrating culture in the productive sectors of the economy. Traditionally, cultural and creative activities that have a higher affinity with manufacturing, such as design and fashion, are considered as belonging to the 'traditional' manufacturing sector, rather than to the cultural and creative sectors. As a consequence, the creative sector appears underestimated and there is loss of information on structural interdependencies between the various areas of creativity (Santagata, 2009). On the other hand, Italy has some 'own' relevant and interesting specificities in its system of production which, if properly understood and exploited, could be at the basis for a 'native' strategic, effective and competitive approach, in the global developments scenario.

As for the rest of the continent, different interpretations of cultural industries have been published for Italy, resulting in highly different estimates. According to the KEA study on the economic weight of cultural industries in European countries, the share of the cultural sector in 2003 was 2.3% of Italy's GDP (KEA, 2006). One year later, the Italy's 'White Book on Creativity' estimated the weight of the cultural sector at 9.3% of the 2004s GDP, by factoring in the entire value chain production related to culture and creativity (including distribution), and by adding up 'Enogastronomia' to fashion and design for a more comprehensive description of the Made in Italy (Santagata 2009). The recent study 'Io sono Cultura' gave a different assessment, reflecting a methodological approach, which

is similar to the KEAs conceptual classification, but rather more inclusive. According to this study, in 2013 the cultural industries share in the country's GDP was 5.4%. This sector accounts for 7.3% of the total industries and for 5.8% of the total employment (Symbolia, 2014). 'L'indagine Civita', avowedly in line with the ESSnet-Culture approach but adopting a more restrictive definition, maintains that in 2010 the cultural and creative industries account for 4.5% of the total industries and for 2.3% of the total employment (Valentini, 2012). These figures confirm what we have argued ever since, that is the resulting fallacious image of the cultural sector, determined by the lack of univocal criteria for its delimitation.

4.3 Impact of the creative sector: an example in Greater Rome

To illustrate this aspect, hereinafter we compare three classification schemes and the resulting delimitation of the CCIs sector in Greater Rome, in year 2009. The data used for this purpose are from The Statistical Archive of Local Units of Active Enterprises (Archivio Statistico delle Unità Locali delle Imprese Attive: ASIA-UL), provided by the National Institute of Statistics (ISTAT)⁶. This is a business register annually updated through a process of integration of administrative and statistical sources. ASIA-UL is constituted by economic units exercising trades and professions in industrial commercial and services activities. The data concern the economic activity (5 digit ATECO code), the legal form and the number of employees of local units dependent on the main enterprise, being active for at least six months during the reference year. ATECO database refers to private economic activities only, thus cultural activities owned by the state are invisible to classification schemes that make use of this data.

The first definition is from the 'Report on the creative industries' by DCMS, that uses 5 digit SIC codes (De Propris et al., 2009), adapted for the Italian ATECO categories. According to this definition, for every creative sector activities are classified in 'layers', which can be interpreted as stages in a creative value chain. Content creation is located at the 'core' and other functions such as distribution and production of complementary outputs lay in the 'periphery' of the classification scheme (Wilkinson, 2007). Layer one includes more intrinsically creative activities located at the top of each supply chain (for example, composition for the music industry, programming for the computer games industry and writing for the

⁶ Data made available by ISTAT according to a research agreement with the Faculty of Economics of Roma Tre University.

publishing industry). Layer two includes those activities that directly support layer one activities in the supply chain (for example, casting for the performing arts). Layer three includes the manufacture of the hardware that directly supports the creative process (for example, the manufacture of television cameras and other hardware directly used in creating television programmes). Layer four includes the manufacture and wholesale of raw materials and the manufacture of hardware used in the consumption of creative industry products (for example, arcade machines for computer games). Layer five includes the sales of creative products (for example the sale of games consoles for the computer games industry). This value chain approach is aligned with other international models, such as the one by UNCTAD (2008) and, to a certain extent, can be considered as a precursor of the ESSnet-Culture (2012) concept of 'economic functions'.

Two Italian classifications ('Io sono cultura' (ISC) and 'Civita') are compared to the DCMS 'reference definition', taken as a whole and, successively, restricted only to the intrinsically creative activities and the activities that directly support them (layers one and two). Table 4-1 and Table 4-2 report the number of creative firms and employees respectively, in the year of observation 2009. Sectors are grouped according to their belonging to the conceptual fields of 'arts', 'cultural industries' or 'creative industries', to allow an assessment of their specific weight according to the different classifications.

When looking at absolute values, we find that the CCIs sector counts for almost 30% of the firms in Greater Rome, if we consider the DCMS inclusive definition. This feature drops down to 6.30% when the restrictive definition by 'Civita' is applied. The 'in-between' classification by ISC returns an estimate on almost 14% of share, which is in line with current estimates of the CCIs share in metropolitan areas in advanced economies (Scott, 2000).

The weight of the CCIs sector reduces when we look at the employment features, which reveal lower percentages of share if compared to the number of firms. This may be explained by the very high incidence of SMEs, in the DCMS and in the Civita classifications. The ISC classification is an exception, since its weight compared to the whole production system in the study area remains similar both for the number of firms and for the number of employees.

The principal difference between this classification and the one by Civita is the inclusion of a major number of 'related' industries in the fields of performing arts, books and press, music, as well as the sector of 'style', composed by manufacture activities related to fashion and high-end industries (jewellery, watches, accessories, cosmetics, furniture, gastronomy).

	Sectors	DCMS	DCMS-LIL2	ISC	CIVITA
	Visual arts	961	755	961	961
ARTS	Performing arts	5 204	4 428	5 283	3 739
	Heritage	122	122	122	50
	Books and press	7 133	3 777	5 717	3 892
CULTURAL	Film, video, radio and TV	2 340	1,843	2 200	2 175
INDUSTRIES	Video games and software	7 579	5 918	5 923	5

Table 4.2 – Employment in the CCIs industries in 2009 in Greater Rome, according to the different classification schemes.

These industries, omitted by Civita classification, account for a larger employment share if compared to the micro-firms that are typical of the creative sector. The same holds for some 'support' segments, such as construction activities for architecture, which have been included as a whole in the DCMS classification, causing the employment share to shrink, if compared to the number of industries.

Another striking feature relates to the differences between the DCMS classification, considered in its restricted form of 'core' activities only (L1 and L2 layers), and the classification by Civita, which admittedly leaves out of the CCIs sector all production and trade activities. To illustrate this we take as an example the music subcategory. If we look at the ATECO codes inherent to music, we find 'music recording activities' and 'editions of printed music'. These activities are included by the Civita classification but excluded in the DCMS-L1L2 classification, none of them being 'content creation' activities.

Figure 4.2 illustrates the robustness of the definition of various subsectors within different classifications. For each subsector we have identified the ATECO codes used at least once by the classification schemes and counted the percentage of activities that are included and excluded in each subcategory. We observe that ATECO codes associations belonging to: visual arts, heritage, design and advertising activities are fully included in the three classification schemes. Performing arts, video, film, radio and television also show a high degree of inclusion, while the rest of the sectors are included or excluded at different degrees in the classification schemes. These are the areas with greater economic relevance: architecture, style, video games and software, books and press. In addition, their value chains are more complex, so as subjectivity in the selection criteria may easily occur, causing discrepancies and imbalances (for example: one would tend to include the construction of musical instruments in the classification scheme, but would think twice before including the construction firms).

Perhaps this evidence provides some explanation for highly discordant numbers and the blurred boundaries of the CCIs sector. Discrepancies become evident when comparing national classifications. Each county has productive sectors that count more than others, depending on the historical, cultural and economic context; CCIs numbers are function of these peculiarities. Therefore, it is hardly surprising the fact that the UK includes the whole software sector and Italy the whole 'style' sector.

Figure 4.2 – Level of inclusiveness of the CCIs sectorsaccording to the different classification schemes.

Figure 4.3 illustrates the specific weight of the creative activities (design, style, architecture and advertising) within each classification. In the case of DCMS this feature counts something more than 80% of the total CCI sector. The two Italian classifications have similar proportions (a bit less than 70%), although having different dimensions. The more extensive the creative sector, the greater is the share of productive sectors in the value chain, and the presence of activities operating in the field of High Tech. These are highly attractive to policy makers, because of their capacity to boost access to funds.

Figure 4.3 – Relative weight of the creative macro sector within the CCIs, according to the different classification schemes. The inner circle represents the number of firms, the outer circle represents the number of employees.

In this context the EU efforts for better comparability of the cultural sectors, through the establishment of a common methodology for data production, is valuable. Being aware of the definition dilemma, ESSnet – Culture 'recommends strongly when speaking about cultural and creative industries, to clearly mention the sectors that are covered, so that the scope is clearly indicated for the sake of comparability' (European Commission, 2012).

Even though there are conflicting accounts on sectorial data, it is clear by now that manufacture activities related to fashion and high-end industries make up the bulk of the economic weight of creative industries. This might perhaps be an explanation for the drift that economic policies for cultural and creative industries have taken during the last decade. As pointed out in chapter 3, innovation, entrepreneurship and market development are the most popular economic policies for creative industries, that have recently started to apply also to funds for general industries, such as startup funds or technology funds (Braun and Lavagna, 2007), appearing perfectly alienated with the fact that EU structural funds support mainly research and innovation (networks, entrepreneurship, SMEs, clusters), information society (digitisation), education, urban requalification (in the framework of integrated projects), investment in human capital, while funding for purely culture-based projects is considerably less (CESS, 2010).

The quantitative economic irrelevance of arts and culture, evidenced by numerous mapping documents, puts them markedly below their potential to contribute towards the achievement of the European Union's Cohesion policy. Considering the cultural sector as part of the wider creative economy may distort cultural policy objectives, losing sight of the important public benefits provided by culture and of the reasons for public support.

PART II

CREATIVE INDUSTRIES AND THE URBAN MILIEU

Chapter 5

Creative clusters

5.1 The creative city and the creative class

Creative industries represent from 4 to 8 per cent of total employment in the most advanced economies, and their relative importance is growing rapidly. In the case of major metropolitan areas like New York, Los Angeles, London, Paris, Milan, Tokyo, the incidence of employment in the cultural economy may rise to levels as high as 25 to 40 per cent of the total employment (Scott, 2000).

One key characteristic of the creative economy is the extent to which it is an urban, and a global city, phenomenon; the creative energies of this field are powered by the production system of the urban environment (Storper and Scott, 2009), since creativity and its specific forms of expression are part of the complex socio-spatial relationships and rooted in the economic activities, employment, and local labour market dynamics of the city. The superiority of dense and diversified urban areas in the transfer of knowledge and innovation output has clearly emerged in research over the last decades (Henderson et al., 1995; Feldman and Audretsch, 1999; Duranton and Puga, 2001; Audretsch, 2002; Andersson et al., 2005; Boshma and Iammarino, 2009). Conceptually these topics are related to the idea of innovative *milieu* (Aydalot, 1986; Camagni, 1991; Ratti *et al*, 1997). An innovative *milieu* is defined as "*the set of relationships that occur within a given geographical area that bring unity to a production system, economic actors, and an industrial culture, that generate a localized dynamic process of collective learning and that acts as* an uncertainty-reducing mechanism in the innovation process" (Camagni, 1995).

Relationships between city and the innovative milieu are analysed in a conceptual perspective by Camagni (1999), who identifies two distinct forms of interaction: i) cities operating as innovative *milieu*, and ii) innovative urban milieu, the latest consisting of well-defined areas located inside the city, where economic activities intrinsically exploit the urban atmosphere. In both cases proximity is crucial, if we consider that close interaction and cooperation amongst firms as well as externalities associated with specialized labour markets are factors that enhance the competitiveness of the local production systems, often made up of small businesses, which find the necessary externalities in terms of infrastructure and services offered by the urban environment (Leone e Struvk, 1976; Pred, 1977). Whereas city is the natural place for the development of creative industries, it goes without saving that understanding the characteristics and the functioning of innovative urban *milieu* is of crucial importance in the study of the creative sector. It is clear, even trough simple descriptive statistics, that the recent rapid proliferation of creative firms occur mostly in large and dense urban areas, while many consolidated metropolitan areas have fully developed 'marshallian' creative clusters (Scott, 2010).

The tendency of creative industries to cluster in metropolitan areas, widely illustrated in scientific literature is explained by the benefits derived from localization/specialization economies (Mommaas, 2004; Cooke and Lazzeretti, 2008; De Propris et al., 2009; Lazzeretti et al., 2012) and, in more 'inclusive' terms, by the existence of the innovative *milieu*, character-istic of specific urban/metropolitan areas (Aydalot, 1986; Camagni, 1991).

Since early 2000s, another research field has emerged focusing on the creative class and their effects in boosting economic performance of global cities. This research field has been significantly marked by the controversial thesis of Florida (2002, 2004) on the rise of the 'creative class' and its role in the regional development. This approach, conceived in a North American context, has undergone increasing popularity in Europe, as reflected by the European research program 'Creativity in European cities' coordinated by Asheim and Gertler (Asheim, 2009), the work of Andersen and Lorenzen (2007) on the Netherlands and work of Chantelot (2006, 2009) applied to France.

Florida's thesis can be reassumed as follows: creativity has become the key individual competence in the knowledge economy, giving rise to the emergence of a distinct 'creative class'; the presence of creative people has become the driving force of local economic development, promoting innovation and production of knowledge; the capacity of cities to attract creative individuals in their choice of residential location, fosters the loca-

tion of knowledge-intensive activities and job creation; the high sensitivity of creative people towards a specific group of urban amenities promotes tolerance and openness.

This approach introduces important innovations in the field of urban economics. First of all, it substitutes the traditional measures of human capital, education and qualification, by new evaluation criterions: typologies and components of the creative class are assessed by means of a set of innovative indicators and nomenclatures, such as tolerance, bohemian index or gay index, for more heavily discussed and criticized (Tremblay et Tremblay, 2010).

Several studies have highlighted the fragility of the empirical correlations between creativity and economic performance of cities arguing that traditional indicators of human capital returned comparable (or better) results (Glaeser, 2005; Donegan et al., 2008). Storper and Scott (2009) severely criticized the excessive focus on residential amenities as the foundation of the metropolitan dynamics and pointed out the theoretical weaknesses of this approach who neglect the essential, structural contribution of productive logics as well as institutional forms by which the concentration of human capital can generate creative innovation dynamics and collective knowledge (Landry, 2000; Rosenthal and Strange, 2004). These limitations have contributed to the academic debate on better defining the concept of creativity, the role of artistic and cultural professions (Scott, 2010; Markusen, 2006) the processes, the determinants for creative clustering (Scott, 2006) and their impacts (Markusen and King, 2003; Lee et al., 2004; Lacour and Puissant, 2007; Asheim and Hansen, 2009).

The (ideal) conditions towards which some of the most advanced creative cities with dynamic cultural economies seem to approach in recent years, are schematized by Scott (2010) in figure 5.1. This scheme, conceptually reminiscent of the value chains approach, constitutes a fairly successful attempt to represent the driving forces of the cultural economy in terms of increment/decrement relationships. The arrangement of elements recalls, symbolically, spatially concentrated processes. Urban space, as a container of knowledge, traditions, memories, and images, is an important component in the creative mix of inter-firm networks and local labour market relationships. As Scott (2010) points out, describing some great city-regions of the modern world like New York, London and Paris, "... parts of these cities display a more or less organic continuity between the local physical environment (as expressed in streetscapes and architecture), associated social and cultural amenities (museums, art galleries, theatres, shopping and entertainment facilities, and so on), and adjacent industrial commercial districts specializing in activities such as advertising, graphic arts, audiovisual production, publishing, or fashion design...

These complex urban ecologies furnish many of the raw materials of the contemporary cultural economy". The process of gentrification, that characterizes parts of consolidated cities, encourage the concentration of skilled people providing them access to creative work basins and cultural amenities. Creative clusters embedded in residential neighbourhoods, support processes of urban regeneration and contribute to creating employment (Del Castillo and Haarich, 2004).

Figure 5.1 – Schematic representation of the creative field of the city (from Scott, 2010).

5.2 Why it is difficult to analyse clusters?

The interest towards the spatial analysis of economic issues has grown since the publication in 1991 of Geography and Trade, by Paul Krugman. By proving the incentive to migrate towards urban areas, both for firms and individuals, the core-periphery model proposed by Krugman, launched the so-called 'new economic geography', contributing to its integration with mainstream economics (Fujita and Krugman, 1995; Fujita, Krugman and Venables, 1999; Fujita, Krugman and Mori, 1999). In this context, it has become clear that the study of spatial concentration of economic activities can shed light on economic theoretic hypotheses concerning the nature of increasing returns and the determinants of agglomeration (Glaeser and Maré, 2001; Eaton and Eckstein, 1997; Peri, 1998; Black and Henderson, 1999; Charlot and Duranton, 2004; Rosenthal and Strange, 2008). There is extensive evidence in literature about the fact that spatial concentration of firms in urban areas determines their access to a more extensive and specialised labour pool. Moreover, firms gain access to a greater range and quality of shared inputs and supporting services and take advantage from the 'knowledge spillovers' that help to disseminate good practice and facilitate new products and processes (Lash and Urry, 1994; Scott, 2001; Duranton and Puga, 2005; Van Widen et al., 2007).

Clusters became an economic development paradigm in regional economic policy, thanks to the work of Porter (1990; 1996; 1998) that promoted the role of industrial clusters in raising regional productivity and innovative capacity. Porter's research, mostly derived by case studies, pointed out the fact that clusters can act as a centripetal force, able to contrast the centrifugal forces of contemporary globalization processes (dispersion of firm activity through outsourcing and offshoring). Thus, clusters encourage local competition and new business formation, contributing to the integration of firms in the local economy (Woodward et al., 2009).

Despite broad success of the cluster concept in various policy-making levels, the cluster approach is frequently criticised in academic literature. A general 'disturbing' aspect is related to the confusion/lack of clarity in the basic terminology of clusters, but criticism embraces also methodological aspects. Martin and Sunley (2003) remark that the vagueness/fuzziness of Porter's 'neo-Marshallian' cluster concept does not lend to easy or precise delineation, with the consequence that ... there is no agreed method for identifying and mapping clusters, either in terms of the key variables that should be measured or the procedures by which the geographical boundaries of clusters should be determined'. Woodward et al. (2009) admit that, on Porter's definition, clusters are hard to identify and track over time. Malmberg and Power (2005), point at the fact that there is little evidence of the effects of clustering and '... the evidence that does exist does not seem to show what we want them to show...'. Glasmeier (2000) argues that the benefits realized from geographical clustering appear to be specific to certain industries at certain stages of development in certain places, and are only realized under particular conditions. Writing about regional advantage and platform policies, Asheim, Boschma and Cooke

(2011), bring evidence about the cluster perspective looking (already) an *'old fashioned'* policy model for platform technologies such as software, displaying pervasive characteristics and complex interactions that are beyond conventional sectorial-spatial notions such as clusters.

Conceptual and methodological issues on cluster definition are further affected by the long-running controversy between supporters of 'Marshall' and 'Jacobs' economies that is far from being resolved (Beaudry and Schiffauerova, 2009). The debate is on whether agglomeration economies or urbanization economies are more important and beneficial (Glaeser et al., 1992; Henderson et al., 1995; Feldman, 2000; Audrechst and Feldman, 1996). Recently, a new stream of research presents a more nuanced view of the benefits brought by 'specialisation' and 'diversity'. Proponents of the 'related variety' concept have argued that beneficial externalities are more important in geographical areas where diverse sectors are able to develop intense relationships. Variety is a source of competitive advantage for the firms located in a place, but only if the diverse sectors that are located together have complementary capabilities and resources. In these cases, 'knowledge spillovers' take place around a 'theme', rather than around a sector (Asheim et al., 2007; Boschma and Iammarino, 2009).

Indeed, cluster definition is a complex task, strongly related to the identification of the causes of concentration. Gordon and McCann (2000) distinguish three stylized forms of spatial clustering, depending on the dominant or characteristic process occurring in the cluster: pure agglomeration, based on geographical proximity and agglomeration economies; industrial complex, based on input-output linkages and co-location in order to minimize transactions costs; and social-network, based on high levels of embeddedness and social integration.

As cluster analysis is rooted in regional studies, urban clusters are an isolated and rather scarce branch of research. Martin and Sunley (2003) point out the fact that most of the studies on industrial clustering follow top-down approaches that make use of large-scale geographical units, such as states or regions, making the assumption that sectorial employment values for these units provide a direct measure of the strength of cluster development. Martin and Sunley (2003) explain that '... extensive methodologies of top-down mapping exercises can at best only suggest the existence and location of possible clusters: they provide a shallow, indirect view of clusters. They cannot provide much about the nature and strength of local inter-firm linkages, knowledge spillovers, social networks and institutional support structures, argued to be the defining and distinctive features of clusters'.

Writing about the state of the art in the study of the spatial localization of economic activities, Duranton and Overman (2008), assert that there is still much work to be done to understand the localization of industries at urban level. This observation is proven to be correct by many studies conducted in the meantime. It draws attention towards an important issue in the study of the distribution patterns of industries, in general, and of the creative industries in particular, revealing that there is a gap between regional studies and studies at the urban scale focusing on the analysis of distribution patterns. This gap deserves further attention and deeper analysis.

Besides observation level, there is another gap between theoretical teachings (and controversies) and mapping clusters exercises: most of the studies on cluster mappings have focused on a particular industry, or involved methodologies in which an industry has been selected as representative of a place (e.g. Becattini et al. 2009), while issues such as the spatial patterns of location and co-location of clusters sharing the same geographical space, are some of the most neglected aspects in cluster literature. This is probably due to the fact that 'cluster is a spatial concept in which a-spatial processes play a prominent role' (Boschma and Klosterman, 2005). Simplifications operated in different empirical studies highlight the true difficulty of dealing with the geographical and functional complexity of cluster components, widely recognized by cluster theorists. At present, the feasibility of working with detailed data on single firm location and activity, opens interesting research opportunities in this field.

5.3 Spatial cluster modelling

Statistical techniques for modelling geographic concentration of economic activities both on a discrete space and on a continuous space are relatively recent. According to Anselin (2006), it is possible to distinguish between two empirical approaches to spatial analysis: spatial econometrics and spatial statistics: the first approach is concerned with the introduction of spatial effects in regression analysis (Anselin, 1988); the second one refers to statistical models enabling for the analysis of spatially referenced data (Ripley, 1981). This latest research brunch focuses on characterizing the spatial distribution of economic activities with respect to a set of hypotheses.

Different measures of spatial concentration have been developed in literature. A first group derives from the Gini coefficient that introduced distribution inequalities (Gini, 1912). Space played no role in these measures, in the sense that they do not rely on any discretization scheme (e.g. Kurgman, 1991). Space is taken into account in aggregated indexes of spatial concentration, such as the Hirschman-Herfindhal index (HHI), or the Ellison and Glaeser index (EG); the latest is a measure that takes into account space and controls for the underlying industrial concentration (Ellison and Glaeser, 1997). The most widely used measure for spatial concentration of economic activities is perhaps the location quotient (LQ) coined by Porter in 1990. LQ was the expedient for introducing the concept of industrial clusters at the basis of economic development policies, both in international and national levels.

Drawbacks of spatial concentration measures have been widely discussed in scientific literature. For example, Martin and Sunley (2003) argued that, when using location quotients, we look at measures of regional specialization, not at clusters. Feser (2000) found that in applied work the EG index is sensitive to the level of spatial aggregation. Spatial aggregation is indeed a bone of content amongst spatial statisticians. The above-mentioned measures of spatial concentration use data aggregated according to pre-defined spatial units. Space, which is naturally continuous, is thus subjected to representation models, which rely substantially on administrative subdivisions at various geographical scales. This problem is known in the statistical literature as the Modifiable Areal Unit Problem (Gehlke and Biehl, 1934; Yule and Kendall, 1950; Openshaw, 1984; Arbia, 1989; Cressie, 1993). The modifiable areal unit problem (MAUP) is a source of statistical bias that can radically affect the results of statistical hypothesis tests, since subdividing a continuous space in a set of discrete spatial units leads to spurious correlations across aggregated variables (Duranton and Overman, 2005; Combes et al., 2008; Briant et al., 2010). These effects can be overcome by using a continuous approach to space, where data are collected at the maximum level of spatial disaggregation, i.e. each industry is identified by its geographic coordinate (x, y), and spatial concentration is detected by referring to the distribution of distances amongst observations. Theoretical aspects of distance-based spatial concentration measures are discussed in detail in many publications (Ripley, 1976; Diggle, 1983; Cressie, 1993; Stoyan and Stoyan, 1995; Upton and Fingleton, 1985; Baddeley et al., 2000).

Unlike other fields, such as ecology or epidemiology, distance-based methods are rather new in economics (Barff, 1987; Sweeney and Feser, 1998). Duranton and Overman (2005) provide exhaustive account of the advantages deriving from the use of these methods in economic studies. The localization processes of industries can be analysed in terms of different forms of spatial association (Arbia et. al., 2008) or relative concentration (Duranton and Overman, 2005; Marcon and Puech, 2010; Espa et al., 2010a), by means of univariate, bivariate or multivariate generalizations used to describe relationships between point patterns.

As already mentioned, measures that treat space as continuous can overcome discretization problems (Feser and Sweeney, 2002; Duranton and Overman, 2005; 2008; Marcon and Puech, 2010), provided that detailed information on localization patterns of phenomena exists. Point pattern analysis is a group of statistical techniques that aim to identify patterns in spatial data. Spatial point patterns are formalized as: univariate, bivariate, inhomogeneous, marked or space-time patterns. Paradigmatic examples of spatial point patters are: a) aggregated pattern, b) regular pattern, c) random pattern (Schabenberger and Gotway, 2005).

In the spatial domain, it is possible to view an aggregated pattern in different ways depending on the focus of the analysis. Generally, aggregations are considered as originated by random effects, which are governed by global model parameters, controlling for the scale and frequency of aggregations. This is similar to the geostatistical view of random processes, where the intensity or local density of events is defined by some type of spatial process. The peaks of this process would correspond with local aggregations. Examples of this approach can be found in Cressie (1993) and Diggle et al. (1983). Point processes based in inferential methods involve comparisons between empirical summary measures and theoretical summary measures of an underlying point process. The basic probabilistic assumptions are stationarity and isotropy: stationarity implies that all properties of the process are invariant under translation; isotropy implies that all properties of the process are invariant under rotation.

The null hypothesis to be tested is the one of Complete Spatial Randomness (CSR) that implies (i) constant propensity of space to host points (uniformity) and (ii) absence of spatial interactions amongst points; i.e. each point's location is independent from the other points' locations (independence).

The homogeneous Poisson process represents an idealized standard of the hypothesis of CSR: (i) for any constant point intensity λ , the number of points located in an area A, follows a Poisson distribution with mean $\lambda | A |$; (ii) the *n* points in A constitute an independent random sample from the uniform distribution on A. Observed pattern distributions that deviate from complete spatial randomness hypothesis include aggregated patterns or inhibitory patterns. Under the null hypothesis of CSR, second order properties can be described by the function introduced by Ripley (1976; 1977), and named Ripley's *K*-function.

$$\lambda K(d) = E[\# of points with distance \le d | at x]$$
 (5-1)

where:

 λ is the intensity of the point process;

K() is an interpoint distance distribution function: $K(d) \rightarrow \infty$ as $d \rightarrow \infty$.

Ripley (1979) suggests a simple estimator for K() in (1), that accounts for edge effects correction:

$$\widehat{K}_{0}(d) = \frac{1}{\lambda n} \sum_{i=1}^{n} \#(\text{other points within distance } d \text{ of } x_{i})$$
(5-2)

where n is the number of points in the area with radius d.

Bivariate K functions are based on the Ripley's K-function but refer to two different sets of points (for instance, type *i* and type *j*). Thus, a bivariate K function is defined as the expected number of type *i* points falling at a distance $\leq d$ from an arbitrary type *j* point. The most widely used estimator for bivariate K function is by Lotwick and Silverman (1982), which is also implemented in SPlancs package in R.

The application of statistical methods based on bivariate point patterns for the study of economic activities allows unveiling co-agglomeration and/or repulsion tendencies amongst pairs of industrial activities. Null hypothesis specification for bivariate patterns in economic applications is rather complex. This is due to the fact that localization processes of two different industries may be influenced by exogenous factors, as well as by mutual relationships between firms. Arbia et al. (2008) suggest two possible definitions of null hypothesis, depending on the study object and characteristics: a null hypothesis of *independence* and a null hypothesis of *random labelling*.

Under the hypothesis of *independence*, it is assumed that type *i* and type *j* point patterns are generated, respectively, by two different and independent univariate point processes. The absence of interaction between them is to be interpreted as lack of interaction between the two generating fields (Lotwick and Silverman, 1982). Under this hypothesis, $H_0:K_{ij}(d) = \pi d^2$. Agglomeration is observed when inside a circle with radius *d* centred on an arbitrary type *i* point, the number of type *j* points is higher than expected under the H_0 , then, $K_{ij}(d) > \pi d^2$. On the contrary, inhibition takes place when $K_{ij}(d) < \pi d^2$. To verify whether observed distribution of firms differs from random distribution, confidence intervals are generated by simulating a large number of independent distributions generated by Monte Carlo simulations (Besag and Diggle, 1977).

Under the hypothesis of *random labelling* a firm can belong randomly to type *i* or type *j*. In the case of economic activities, this can be interpreted as the existence of conditions that encourage location of one industry rather than the other. Under this hypothesis: $H_0:K_{ij}(d) = K_{ji}(d) = K(d)$ (Diggle and Chetwynd, 1991).

The null hypothesis of *random labelling* is evaluated by computing the

pairwise differences between the various *K* functions and by comparing them with simulated confidence bands (Diggle and Chetwynd, 1991; Gatrell et al., 1996; Kulldorff, 1998; Dixon, 2002; Haining, 2003). Agglomeration is observed when $K_i(d) = K_{ij}(d) - K_j(d) > K(d)$, inhibition is observed when $K_{ij}(d) = K_i(d) - K_j(d) < K(d)$. Confidence intervals are generated using Monte Carlo simulations, by keeping firm's location unchanged and by randomly assigning the labels that characterize each sector.

Over the last decade exhaustive account it was given about the advantages deriving from the use of distance-based methods in economic studies. Notwithstanding, empirical applications are still limited (Arbia and Espa, 1996; Duranton and Overman, 2005; 2008; Marcon and Puech, 2003; 2010; Quah and Simpson, 2003; Arbia et al., 2008; Espa et al., 2010a). Bivariate K-function is the most widely used method amongst the economic applications of point-pattern analysis, because it enables for rather straightforward testing procedure for spatial association between pairs of sectors. There are also other empirical examples of the application of K-functions for mark-weighted patterns (Espa et al., 2010b) and space-time patterns (Arbia et al., 2010).

The use of distance-based statistical methods to analyse the location patterns of creative industries appears a promising research field. Indeed, a closer look on the creative clusters, their physical extension and their components, would facilitate interpretation and give precious insights of the types of relationships that take place within these complex spatial arrangements.

5.4 Why studying creative clusters?

The influence of creative industries in economic development is generally studied according to two main research lines: spatial aggregation of creative firms and their determinants (Scott, 2006; Lazzeretti et. al., 2012; Marrocu and Paci, 2012; De Miguel Molina et al., 2012); influence of creative people in employment growth (Florida, 2002; 2004; Scott, 2010). The analysis of localization of creative firms is very recent (Boix et al., 2012), as studies of this kind so far have privileged the manufacturing sector. The scarcity of detailed studies on location patterns of creative industries is, to a certain extent, arguable in the light of the difficulties to provide a clear definition of the creative sector (Garnham, 2005; Evans, 2009; Scott, 2010; Flew, 2010) and of fact that creative activities are in part invisible to data collection (Girard, 1982). If we consider also the difficulty to produce (and to obtain) disaggregated data on economic activities in general and on the creative sectors in particular, we can figure out why point-pattern analysis has not yet been applied to this economic sector.

Despite criticisms and controversies characterizing the cluster concept, it is widely accepted that creative industries show a clear tendency to concentrate in dense urban environments, typically, metropolitan areas. In distinction from manufacturing clusters, the relevant factors for explaining the clustering of creative industries (i.e. services with a symbolic knowledge base) are not only the benefits of localization (and specialization) economies, but also, in great part, the effects of old and new types of urbanization economies (Mommaas, 2004; Cooke and Lazzeretti, 2008; De Propris et al., 2009; Lazzeretti et al., 2012). Urbanization economies typically produce location patterns of cluster overlapping. Co-location provides cross-fertilization urbanization economies (Jacobs, 1969; 1984; Lorenzen and Frederiksen, 2008), opportunities for the co-presence of related variety (Boschma and Frenken, 2011), buzz (Storper and Venables, 2004), and access to collective learning and shared knowledge resources (Keeble and Nachum, 2002).

Localization patterns can be monocentric or polycentric, according to the city size and functional characteristics. Typically, large cities, with sensible land rents variation are characterized by polycentric distribution of activities and functions. In these conditions clusters of the same activity can be found in different parts of the city, partially overlapping with clusters of other activities and taking the form of clouds of clusters. Such patterns cannot be observed through a macro-scale perspective, for this reason, the micro-scale analysis becomes indispensable to capture specific cluster characteristics (Boix et al., 2012).

De Propris and Hypponen (2008) define a creative cluster a place that brings together: a) a community of 'creative people' who share an interest in novelty but not necessarily in the same subject; b) a catalysing place where people, relationships, ideas and talents can spark each other; c) an environment that offers diversity, stimuli and freedom of expression; and finally d) a thick, open and ever changing network of inter-personal exchanges that nurture individuals' uniqueness and identity. Britain's Department of Culture Media and Sports (DCMS), following its seminal (and highly discussed) approach on creative industries, defines creative clusters as 'groups of competing and co-operating businesses that enhance demand for specialist labour and supply networks in a particular location. Such infrastructure depends not only upon the vitality of the creative sector itself, it is also underpinned by public policy and significant public investment' (DCMS, 2006).

As evidenced by the literature, the spatial dimension of CIs is treated in research at three different levels: global, regional and local. This hierarchy reflects the fact that creative industries are concentrated in a limited number of densely urbanized areas, many of which are global cities; moreover, they are concentrated in particular neighbourhoods of these cities (Pratt, 2011b). Despite the simultaneous existence of local and global creative economy and increasing levels of inter-relation between them, globalization does not yet appear to prompt cultural homogeneity (Graham, 1999; Camagni, 1999; Scott, 2001a). In a context of attaining its largest spatial reach, thanks to the existence of organizational networks across the globe held by multinational corporations which are moving aggressively into all the segments of new cultural economy (Sassen, 2001), creative production appears even more polycentric and geographically differentiated (Scott, 2010).

The difficulty of analysing CIs from a spatial perspective is also related to the existence of conceptual problems as well as to the methodological awkwardness in facing the complexity of this issue. The first consideration concerns the lack of a clear-cut definition of what creativity represents in economic terms. This aspect in the empirical analyses maybe translated to measurement problems due to either multicollinearity or omitted variable bias. In both cases this leads to confusing evidence as the effects of creativity on local performance are inadequately estimated. Another consideration is that, so far, the literature has not provided a specific theory on creative industry clusters. However, enough is known to indicate that important components of a creative industry cluster theory will differ from traditional theories of manufacturing clusters, and from more recent ones on high-tech clusters. The bases of this difference are rooted on the symbolic knowledge-bases of creative clusters (Asheim et al., 2011). While methods deriving from regional studies find it difficult to identify cluster localization patterns and their determinants, and to describe the effects in small scale urban environments, methods deriving from ecology and similar environmental disciplines, that have typically been adapted to explore more detailed patterns of industry location, are struggling to take off. Since the degree of local economic differentiation and specialization tends to increase as the size of geographical units decreases, applications using small scale data may run the risk of exaggerating the number and significance of clusters. In introducing one of their studies dealing with a generalized spatial point-pattern approach, Duranton and Overman (2006), admit that in this field "... our knowledge is still very patchy".

Geographic concentration of creative firms increases the opportunities for them to interrelate, to employ suitable labour, to benefit from common infrastructure and to reduce market uncertainties. Spatial extension and density of economic activities determine the significance of these benefits. In the context of creative industries, a major challenge would be to test for spatial concentration of firms in the different creative subcategories. Much it has been written about economic activities that should or should not be part of the creative domain (software; advertising; heritage): the study of spatial interactions between creative categories within specific geographical areas, would be a good exercise for identifying and interpreting mutual relationships, and a way of compensating for the arbitrary nature of many definitions. Moreover, testing for co-localization of creative subcategories, would offer indirect evidence of the impact of urbanization economies in clustering of creative industries. It has been widely argued that production chains affect industrial clustering (Turok, 2003). Firms within production chains tend to locate close together to minimize the costs of communication. Good internal and external transport infrastructure and logistics systems are important for the competitiveness of industrial complexes. In the case of creative industries, testing for co-localization between content-creation creative activities and 'support' activities, such as the production and distribution of complementary outputs, would offer direct evidence on the spatial relationships that creative industries hold with the rest of the creative value chain.

Starting from two key assumptions fully argued and in the scientific literature, that: (i) creative clusters are concentrated in (a limited number of) densely urbanized areas and (ii) creative clusters are concentrated in particular neighbourhoods of these cities, in the next session we will try to delineate some typical characteristics/behaviours of the roman case.

CHAPTER 6

A case study in Greater Rome

6.1 Study area

Greater Rome⁷ is located in central Italy and covers an area of 5,352 km², between 42°14' and 41°24' Northern latitude and between 13°18' and 11°44' Western latitude. The study area is in large part occupied by the alluvial plan of the Tiber River and includes in the North-eastern part the volcanic systems of the Sabatino district and the Castelli Romani. The Tirrennean Sea delimits the area to the west.

Greater Rome has 121 municipalities (comuni). The area is dominated by the presence of the city of Rome and its strongly monocentric metropolitan system that accounts for almost 7% of the total Italian population. The municipality of Rome extends for 1.286 km², occupying 24% of the provincial territory. First belt municipalities, related to the capital city by intense interchange flows, occupy 30% of the provincial area. The rest of the territory is divided into small 'peripheral' municipalities. According to the last census, the provincial population amounts at 3,997,465 inhabitants, of whom 65% live in the municipality of Rome, 25% in first belt municipalities and 10% in peripheral ones (Figure 6.1). Upon a concentration of tertiary economic functions in the capital, the 'other' municipalities have developed in the last decades a strong residential specialization.

⁷ Greater Rome corresponds to the administrative region of Metropolitan City of Rome, established as since January 1st 2014 (L. n° 135, 2012), substituting the former Province of Rome.

Figure 6.1 – Monocentric distribution of the population density. Territorial units represent the urban districts composing the municipality of Rome and the rest of municipalities of Greater Rome. Read lines depict first belt municipalities. *Source: Population and Honsing Census, 2011.*

6.2 Data

The data used to analyse the CIs in the study area are from The Statistical Archive of Local Units of Active Enterprises (Archivio Statistico delle Unità Locali delle Imprese Attive: ASIA-UL), already mentioned in section 4.3. For each local unit ASIA-UL provides identification information: name, address, tax code and VAT number, and information about the firms' structure: type of economic activity, legal form, turnover, number of dependent and independent workers. Our dataset refers to the study area in 2009. Personal data are made anonymous but firms are accurately located in space by means of cartographic coordinates (WGS 84 coordinate system), their economic class of activity is highly accurate (5-digit ATECO code), the number of employees of local units dependent on the main enterprise is provided, as well as the number of employees, economic class of activity and the economic turnover of the main enterprise in the reference year. Some problems and difficulties related to the use of the available ASIA-UL dataset for the purpose of analysing the spatial behaviour of the CIs in the study area, include:

- the varying localization accuracy that causes information loss (about 1.5% of the firms are located on the centroid of the municipality of reference; 0.6% are located on the centroid of the postal code area);

- the re-definition of the economic activities nomenclature operated by ISTAT in 2006 that makes it impossible the comparison between ATECO codes pre and post 2007, limiting *de facto* the time interval of the study to the post-2006 period;

- the absence of firm demography. The lack of information about firms' births and deaths makes it impossible the use of a spatial panel if diacronic data are available.

Selection and extraction of creative industries from the dataset is operated on the basis of the definition of creative industries proposed in the 'Geography the creative industries' by DCMS, that uses 5-digit SIC codes (De Propris et al., 2009), adapted for the Italian ATECO categories. According to this definition, for every creative sector activities are classified in 'layers', which can be interpreted as stages in a creative value chain. Content creation is located at the 'core' and other functions such as distribution and production of complementary outputs lay in the 'periphery' of the classification system. Layer one includes more intrinsically creative activities at the top of each supply chain (for example, composition for the music industry, programming for the computer games industry and writing for the publishing industry). Layer two includes those activities that directly support layer one activities in the supply chain (for example, casting for the performing arts, proof-reading or translating for publishing). Layer three includes the manufacture of the hardware that directly supports the creative process (for example, the manufacture of television cameras and other hardware directly used in creating television programmes). Layer four includes the manufacture and wholesale of raw materials and the manufacture of hardware used in the consumption of creative industry products (for example, arcade machines for computer games). Layer five includes the sales of creative products (for example the sale of games consoles for the computer games industry).

6.3 Firm size and share of the creative sector

The data from ASIA-UL show that, in the observation year 2009: 81.14% of economic activities in the creative sectors in Greater Rome are

represented by single employee firms; 17.26% of the firms have from 2 to 20 employees; 0.86% of the firms have from 21 to 50 employees; 0.74% of the firms have more than 50 employees. This feature should not be surprizing. According to the 'innovation incubator hypothesis' (Pred, 1977), the city is the natural place for the development of small businesses, which find the necessary externalities in terms of infrastructure and services (Leone e Struyk, 1976). In the case of the creative sector, the small businesses phenomenon is even more enhanced if compared to other economic contexts, because of the presence of a larger number of self-employed content creators (Hesmondhalgh, 2002; Pratt, 2011a). In the case of Rome, this feature appears extremely pronounced, being the share of self-employed people remarkably higher than the 60-70%, generally indicated at the European level (KEA, 2006).

Table 6.1 summarises the number of creative firms and employees in the year of observation 2009, while Figure 6.2 illustrates the share of the creative sector and of the corresponding support sectors in the Greater Rome according to the above-mentioned DCMS classification.

Creative category	N. Firms	N. Employees
Advertising	1 494	3 529.87
Architecture	11 512	18 263.45
Arts, antiques and crafts activities	2 086	4 339.37
Design activity	315	449.08
Designer fashion	1 591	2 076.43
Music and performing arts	3 739	5 305.72
Publishing	3 705	8 970.50
Radio e TV	292	11 294.05
Software and computer games	5 918	42 208.92
Video, film and photography	2 306	15 599.74
Total	32 958	112 037.13

Table 6.1 – Distribution of creative categories in Greater Rome in 2009.

Source: ASLA-UL 2009.

CIs sector in Greater Rome counts for almost 10% of the total firms, while the share of the service sector reaches the 20%. These features appear to be coherent with CIs shares estimates for other European metropolitan areas (Scott, 2000).

Figure 6.2 – Share of the creative sector in year 2009.

Creative categories proposed by the DCMS definition bring together groups of economic activities that reveal remarkable differences both in terms of specific weight of the various sectors, and in terms of layer composition. It is therefore predictable that different creative categories. although rooted in the urban structure, would establish with it different relationships, resulting in different spatial distributions. Figure 6.3 illustrates the distribution of firms (a) and employees (b) in the creative categories, by layer, in 2009. The number of firms is dominated in the core activities by two creative categories: Architecture and Software and computer games. 'Traditional' cultural industries are represented to a large extent by Music and performing arts, and Video, film and photography. Amongst support activities it is worth to mention the weight of construction firms (L4) in the value chain of Architecture and that of retail of fashion products (L5) in the value chain of Design. Employment in the creative sector is dominated by Software and computer games and by the audio-visuals: Video, film and photography as well as Radio and television. In analogy with the number of firms, employment in the support activities is dominated by the construction firms (L4) in the value chain of Architecture and by the retail of fashion products (L5) in the value chain of Design.

Creative categories greatly differ in terms of firm size. We look closely at this feature for the core activities in Figure 6.4, noticing that: Architecture, Design, Arts, antiques and Crafts, Advertising, are dominated by the presence of single employee firms and micro firms (up to 10 employees). The audiovisuals: Video, film, photography and, in particular, Radio and television are strongly dominated by the presence of large firms (more than 50 employees). The same holds true for Software and computer games.

Figure 6.3 – Firms (a) and employees (b) in the creative categories by layer, in 2009. *Source: ASLA-UL.*

Figure 6.4 – Employees in creative categories by class, in 2009. *Source: ASLA-UL*.

6.4 Spatial distribution of the creative sector

Localization patterns of CIs can be monocentric or polycentric, according to the city size and functional characteristics. Generally, large cities, with sensible land rents variation are characterized by polycentric distribution of activities and functions. In these conditions clusters of the same activity can be found in different parts of the city, partially overlapping with clusters of other activities and taking the form of clouds of clusters. (Boix, Hervas-Oliver, De Miguel-Molina, 2012).

If we look at the percentage of core creative firms over the total of firms in the territorial units of Greater Rome⁸ as a function of their distance from the city centre, we notice a clear negative relationship: the number of units containing a greater share of creative enterprises decreases with increasing distance from the city centre (Figure 6.5).

Figure 6.5 - Creative firms in the spatial units in relation with the distance from the city centre (% over the total of firms).

Therefore, we can assert that the distribution of creative industries in the study area reflects the monocentricity of its urban structure.

Figure 6.6 illustrates the spatial distribution of firms according to their size. From the maps we can observe that, as the size of firms increases, the spatial concentration also increases: single employee firms are distributed all over the region, following the metropolitan urban pattern; firms with up to 20 employees show a very similar distribution pattern but much

⁸ Aggregations are performed on the territorial units as defined in Figure 6.1.

more rarefied; large scale firms are almost exclusively concentrated in the municipal territory of Rome, in particular in the city centre and towards the South.

Figure 6.6 – Point pattern distribution of creative firms in Greater Rome: a) firms with 1 employee; b) firms with 2-20 employees; c) firms with 21-50 employees; d) firms with more than 50 employees.

We can argue that, taken as a whole, CIs show a similar distribution pattern if compared to the rest of economic activities. This pattern generally draws to the urban imprint being, as previously shown, highly monocentric. Large firms are concentrated in some of the central city neighbourhoods. It appears obvious that such patterns cannot be analysed through a macro-scale perspective; thus, the micro-scale analysis becomes indispensable to capture specific cluster characteristics.

Figure 6.7 – LQ of creative firms in 2007. *Source: ASLA-UL.*

We now analyse the degree of specialization level in creative activities in the administrative units of Greater Rome⁹ by calculating location quotients (LQ). Standard LQ (De Propris et *al.*, 2009) is an aggregated measure calculated by computing the ratio between the local (municipal/district) share of the creative industries and the industry's share at metropolitan level. LQ values above one indicate that the local unit has a higher share of creative industries than the metropolitan area as a whole. With respect to the previously described definition of creative industries, the activities considered are those intrinsically creative, located at the top of each supply chain (Layer 1) and those, which directly support layer one activities in the supply chain (Layer 2). Distribution of specialization level in creative activities is illustrated in Figure 6.7. We observe that territorial units with higher share of creative industries are located in form of a cluster with an elongated shape disposed along the north-south direction. This spatial ar-

⁹Due to its large extension, if compared to the rest of the municipalities in the study area, the Municipality of Rome has been further subdivided in urban districts, according to the census nomenclature.

rangement involves part of the consolidated city, part of the southern regions towards the See, and some northern regions along the Via Cassia, in first instance, and then areas located along the motorway A1.

Being not sensitive to absolute values, the LQ index cannot offer a real picture of clusters. Conversely, the mapping of each point location would give a correct perception about the spatial extension of clusters, but not about their intensity. Kernel density mapping accounts for both intensity and spatial extension of the observed phenomena. Distance-based statistical tools used in point-pattern analysis are rooted in the kernel concept.

Figure 6.8 represents the Kernel density estimation depicting the cumulative incidence of creative firms over a gridded surface of the study area. Conceptually, a smoothly curved surface is fitted over each point. The surface value is highest at the location of the point and diminishes with increasing distance from the point, reaching zero at the maximum search radius distance from the point⁹. The perception of cluster in Figure 6.8 is different from the one in Figure 6.7. The spatial extension covers the entire consolidated city and extends beyond the municipal limits in territories that correspond to some of the first-belt municipalities. Spatial concentrations of creative industries are almost absent in peripheral regions of the Metropolitan area. Intensity peaks are clearly visible in Rome's city centre (Prati and Parioli neighbourhoods), in the northern quartier of Fidene, in the southern quartier of EUR, as well as along the motorway that conducts to the Fiumicino airport.

For the single creative sectors, whose Kernel functions are reported in Appendix 2, we can summarise the following: Advertising, Architecture, Design, Music and performing arts, are spatially distributed in accordance to the urban form and extension. Architecture has three different intensity peaks, while the rest of the sectors only one, centrally located, peak. Publishing as well as Arts, antiques and crafts show a similar monocentric distribution pattern, similar to the above-described activities, but their spatial extension is far more reduced. Software and computer games barycentre

$$f(x) = \frac{1}{nb} \sum_{i=1}^{n} H \frac{(x - x_i)}{b}$$

⁹ Kernel density estimation was performed with the Spatial Analyst Extension for ArcGIS 10. ArcGIS employs the quadratic kernel function described in Silverman (1986):

Where *h* is the bandwidth, x_i is the Euclidean distance between type *i* firms. *K* is the quadratic kernel function, which is defined as: $H(x) = -\frac{3}{4}(1-x^2), |x| \le 1; K(x) = 0, x > 1$. We chose a bandwidth (kernel) of 40 km with an output cell size of 100x100m.

is in the southern quartier of EUR, in discordance with the rest of the creative sectors. This sector also displays a significant offshoot along the motorway that conducts to the Fiumicino airport. Radio and television as well as Video, film and photography are highly concentrated in the city centre, both revealing multiple intensity peaks.

The mapping exercise has highlighted the fact that Rome's city centre hosts the largest number of creative activities. Areas of influence of different creative categories have different spatial form and behaviour, but they overlap.

Cartographic representation of spatially distributed phenomena is useful in discovering relationships amongst distributions. These relationships can be further developed through specific statistical techniques that aim at identifying patterns in spatial data.

Figure 6.8 – Kernel function for the creative firms in 2007. *Source: ASLA-UL*.

6.5 Spatial interdependence of firms in the creative sector

There is evidence of spatial concentration of creative firms in Greater Rome. Spatial concentration may or may not support spatial interdependence amongst economic activities. The presence of spatial interdependence is manifested by spatial concentration of similar values (in the case of positive interdependence) or of different values (in the case of negative interdependence). In the literature there exist a large group of tests for verifying the presence of spatial autocorrelation. The most widely used test statistic is the Moran's I (Moran, 1950). The Moran's I is given by the following expression:

$$I = \frac{N}{S} \frac{\sum_{ij}^{N} W_{ij} (x_{i} - \bar{x}) (x_{j} - \bar{x})}{\sum_{i=1}^{N} (x_{i} - \bar{x})^{2}}$$

where

 x_i is the studied variable in region *i*.

 \overline{x} is the average sample value.

 W_{ij} are binary spatial weights: value 1 is given to the spatial units within distance d from the geographic centroid of the spatial unit, and 0 to all other regions.

N is the sample dimension.

$$S = \sum_{i} \Sigma W_{ii}$$

Moran's *I* is generally presented as a standardized measure which, when N is large enough, is distributed as a standard normal. Moran's *I* values range from -1 to +1, with values close to 0 indicating the lack of spatial autocorrelation. Values close to 0 of the Moran's *I* will not reject the null hypothesis of spatial randomness, while positive (or negative) values close to 1 will indicate the presence of significant positive (or negative) spatial autocorrelation.

The other test is LISA statistics, which returns a measure of spatial autocorrelation for each individual location in relation to its neighbours and provides information about which unit values are statistically significant compared to spatial randomness. Spatial autocorrelation can be positive or negative. High values of one variable observed in one location, associated to high values of the same variable observed in adjacent locations (HH) are positive relationships, also identified as 'hot spots' or clusters, since they indicate the tendency of a variable to concentrate in space in particular locations. Low values observed in one location, associated to low values observed in adjacent locations (LL) are positive relationships as well, showing the tendency of a variable toward spatial dispersion. Negative spatial autocorrelation occurs when high values observed in one location are associated to low values observed in adjacent locations (HL), or vice-versa (LH). These types of observations are also called outliers, generally indicating anomalous spatial behaviours or data errors. We have aggregated the number of creative industries by census block in the study area, and computed the Local Moran LISA statistics (Anselin, 1995).

The results of Global Moran's *I* and LISA test statistics for the previously illustrated variables are reported in Table 6.2. Most of the census units are characterised by positive spatial association. A majority of spatial units lie in low-low quadrant. Low-low values associations are to be considered of little interest in this context, since agglomerations of firms are represented only by significant high-high or high-low census block values. The third column in Table 6.2 shows the distribution of census blocks having a significant *p*-value in the quadrants of the Moran scatterplot.

Moran Scatter Plot Quadrant	Total	Significant	% Significant
HH	4 087	2 496	61.07
HL	1 604	341	21.26
LH	3 674	1 504	40.94
LL	10 270	3 213	31.29
Total spatial units	19 635	7 554	38.47

Table 6.2 - Local indicators of spatial association (LISA) statistics. The distribution of significant census units in the quadrants of the Moran scatterplot is expressed as a percentage of the total significant units.

It is interesting to observe that, independently of the number of census blocks located in the various quadrants, the percentage of those with significant *p*-value is much higher for spatial units lying in the high-high quadrant, indicating that spatial clustering of high values ('hot spots') may occur in different areas.

If we take a closer look at the significance levels, we observe that census units having a positive relationship of high values represent almost 53% of the total units with *p*-values significant at p = 0.001. Conversely, the share of census units of this type represents 13% of the total non-significant units. The opposite holds for units having a positive relationship of low values. They have a share of 58% of the total non-significant units, of 51% total units with *p*-values significant at p = 0.05 (weakly significant) and of 19% of the total units with *p*-values significant at p = 0.001 (Table 6.3). These results further support the assumption of the spatial clustering of creative firms in Greater Rome.

Moran Scatter Plot Quadrant	Significance level			
	0.001	0.01	0.05	NS
HH	52.90	31.42	23.43	13.17
HL	7.15	3.14	4.66	10.45
LH	20.74	18.63	21.01	17.96
LL	19.21	46.81	50.90	58.41

Table 6.3 - Significance levels of census units.

It is possible to map the statistically significant Moran's *I* values across the census blocks to identify the location and shape of clusters. Figure 6.9 shows those locations with a significant Local Moran statistic classified by type of spatial correlation: the high-high and low-low locations suggest clustering of similar values, whereas the high-low and low-high locations indicate spatial outliers.

Figure 6.9 - LISA cluster map for creative firms in the census blocks in Greater Rome, 2009.

As it can be observed from the map, spatial clustering of high values ('hot spots') occurs in different areas of the consolidated city. The phenomenon is particularly intense in the neighborhoods just north to the historic centre (Trionfale, Delle Vittorie, Ottaviano, Flaminio, Trieste, Nomentano, Parioli, Tor di Quinto, Monte Sacro). Consistent hot spots are also observed in the weastern neighbourhoods (Aurelio, Gianicolense) and in the southern neighbourhoods (Appio Latino, Vigna Murata, Decima, Mostaciano, Spinaceto, Vallerano). It is significant the quasi absence of creative clusters in the eastern sector of the consolidated city, traditionally industrial, which hosts some of the poorest and infamous neighborhoods of Rome.

Spatial clustering of low values 'cold spots' occurs in peripheral areas of the Metropolitan region. The significant geographical extension of these areas is due to the large dimensions of sparsely populated census units and represents a clear example of the Modifiable Areal Unit Problem (MAUP) (Gehlke and Biehl, 1934; Openshaw, 1984). Spatial outliers of the type high-low, thus interesting from the point of view of the agglomeration dynamics, are represented by a small number of units, mostly located in-between the consolidated city and the peripheral regions. These are typically concentrations of creative industries in small first-belt urban satellites, also affected by the MAUP problem: since the urbanization level of these areas is lower, if compared to those the consolidated city, the census sections have larger dimensions therefore the high-high type of agglomeration amongst census units does not occur.

6.6 Testing for creative industries clustering with bivariate point patterns

In the following sessions we study the location patterns of different creative sectors. We identify and interpret mutual relationships amongst these groups of activities, as well as their interactions with the respective service sectors. Analysis is based on bivariate spatial point patterns introduced in section 5.3.

The selected method to test for industry localization depends on the hypothesis made over the nature of the spatial relationships. Bivariate spatial patterns may be interpreted in terms of exogenous factors influencing both types of economic activities, which lead to joint-localization, or in terms of attraction-repulsion amongst them, which leads to co-localization.

According to Duranton and Overman (2005), tests of industry localization should rely on a measure which: (i) is comparable across the firm types; (ii) controls for the overall agglomeration of firms; (iii) controls for individual concentration; (iv) is unbiased respect to the scale of agglomeration; (v) gives an indication of the significance of the results.

In the context of analysing the localization characteristics of two different types of industries, distance-based methods have the significant advantage of detecting spatial structure at every scale: geographic concentration or dispersion of firms in space is reported independently from the scale of phenomenon (property [iv]). Marcon and Puech (2010) identify two principal groups of distance-based methods used in the economic literature:

- i. The *probability density function* utilised by Duranton and Overman (2005). This measure is based on the average number of neighbours at each distance, smoothed and normalized so that it sums up to 1.
- ii. The *cumulative distance-based methods* based on Ripley's *K*-function (1976, 1977), Besag's *L* function (1977) and their extensions based on the second-order property of point patterns (Barff, 1987; Arbia, 1989; Espa et. al., 2010a; Espa et. al., 2010b). These functions describe geographic concentration by counting the average number of neighbours on every possible circle with a given radius.

Despite some limitations, cumulative distance-based methods based on Ripley's K-function are the most widely used in empirical economic applications. A principal drawback of these methods is related to the fact that they are generally applied to relative concentrations (i.e. detect whether each industry is overrepresented or underrepresented with respect to a baseline distribution), but they refer literally to absolute concentrations, being based on the null hypothesis of completely random spatial distribution of establishments (i.e. plants are distributed uniformly and independently). Property [iii] defned by Duranton and Overman (2005) is usually fulfilled by comparing a sector's distribution with the overall location pattern of industries, yet, Marcon and Puech (2003) maintain that these statistical tools effectively measure the existence of specialized areas only. Another issue is related to the fact that distance-based methods most often do not consider the size of industries (property [ii]), although adaptations of Ripley's K-function to include marked point-patterns that account for industry size, have been proposed in order to overcome this problem (Espa et al., 2010b).

One of the most important concerns about the application of distancebased functions to point-patterns of economic activities is the fact that economic space is heterogeneous. The presence of geographic features such as water bodies or protected areas, where firms cannot locate, is a clear contraindication for the use of statistical methods, which are based on the null hypothesis of completely random spatial distribution of establishments. This aspect is even more enhanced when working with pointpatterns at urban/neighbourhood scale. In these cases, we should account for the fact that firm localization is subject to precise spatial constraints, related to the physical composition of built-up units.

To avoid these restrictions, it is possible to account for space heterogeneity by assuming a null hypothesis of *random labelling* (Diggle and Chetwynd, 1991; Marcon and Puech, 2003; Espa et al., 2010a). This hypothesis implies that the location of firms is fixed, while their sector of activity is distributed randomly. The reference framework is the marked point process (Diggle, 1983) that, besides of the point location, accounts for point characteristics (e.g. type i; type j).

6.7 Aggregative patterns of core creative sectors

We first look at the characteristics of the spatial distribution of different core creative sub-sectors with respect to the rest of core creative activities in the study area (layers L1 and L2). The null hypothesis is the one of random labelling discussed in section 5.3, as proposed by Diggle and Chetwynd (1991), i.e. a firm can belong randomly to one creative sector or to the rest of the creative activities. Under this hypothesis, at any distance d, $K_s(d) = K_C(d)$, where $K_s(d)$ and $K_C(d)$ are Ripley's K-functions for the single creative sector and for the rest of creative economy respectively. The distance-based function is defined as $D_s(d)=K_c(d)$.

Such a difference can help in identifying creative sectors that are overconcentrated (over-dispersed) conditionally upon the spatial pattern displayed by the rest of the creative economy in the study area. D detects the occurrence of statistically significant concentration or dispersion of each creative subsector with the increasing of distance.

Confidence intervals, at a significance level $\alpha = 0.05$, are generated using Monte Carlo simulations, by keeping firm's location unchanged and by randomly assigning the labels that characterize each sector. We apply Dfunction in a study area of 100x150 km that comprises Greater Rome. The distance d is considered 50 km (ibid.). Behaviours of the estimated \hat{D} functions for each creative sector compared to the rest of creative economy are reported in Appendix 3. Figures 6.10 to 6.12 represent three clearly distinguishable distribution patterns of creative sub-sectors observed in the study area. The continuous line is the estimated \hat{D} function, namely the difference between the estimated \hat{K} function for one creative sub-sector and the estimated \hat{K} function for the rest of creative activities. The dotted lines are the simulated confidence bands. They represent the maximum and minimum values D function assumes, after a sequence of 9999 random labellings of the two point data sets (Rowlingson and Diggle, 1993).

Figure 6.10 illustrates a case of over-concentration of one creative sub

sector when compared to the rest of the creative sectors. In this case the estimated \hat{D} curve lies above the maximum envelope curve. Figure 6.11 illustrates a case of random labelling of one creative sub sector when compared to the rest of the creative sectors. In this case the estimated \hat{D} curve lies in-between the maximum and minimum envelope curves.

Figure 6.10 - Agglomeration pattern for the "Publishing" sector in Greater Rome.

Figure 6.11 - Random labelling for the "Architecture" sector in Greater Rome.

90

Figure 6.12 illustrates a case of over-dispersion of one creative sub sector when compared to the rest of the creative sectors. In this case the estimated \hat{D} curve lies below the minimum envelope curve.

Software and computer games

Figure 6.12 - Dispersion pattern for the "Software and computer games" sector Greater Rome.

Table 6.4 reassumes the observed spatial behaviours for all the creative sub-sectors. The third and fourth columns indicate the existence of concentration and dispersion patterns, respectively, and the distance at which these phenomena occur. The fifth column evidences the distance at which intensity peaks are observed. The lack of reference values both for concentration and for dispersion patterns evidences random labelling of one subsector when compared to the spatial distribution of rest of creative activities.

Creative category	N. Firms	Concentration	Dispersion	Peak
Advertising	2 052	0-7.5 km		6.5 km
Architecture	11 562			
Arts, antiques and crafts	4 108	0-11 km		5 km
Design	1 522			
Music and performing arts	4 921	0-48 km		10 km
Publishing	2 789	0-40 km		8 km
Radio e TV	322	0-12 km		8 km
Software and computer game	s 5781		0-15 km	9 km
Video, film and photography	2 340	0-33 km		8 km

Table 6.4 - Concentration-dispersion characteristics for each creative sector in Greater Rome.

From Table 6.4 we learn that: Advertising; Arts, antiques and crafts; Music and performing arts; Publishing; Radio and television; Video, film and photography, display a pattern of *significant concentration* when compared to the spatial distribution of rest of creative activities; Software and computer games has a spatial pattern of *significant dispersion*; Architecture and Design are *randomly labelled*. The distance at which there is significant concentration differs greatly between the various creative sectors. A common characteristic is the existence of only one concentration peak for all nonrandomly labelled categories. This feature derives from the strong monocentric pattern of Rome's Metropolitan area.

The localization characteristics displayed by the different creative sectors are interesting to comment in the light of the strong differences between the components. The arts and the media, which are the 'traditional' categories of the 'cultural' economy, have a clear tendency to agglomerate if compared to the totality of the creative activities of the city. Creative sectors such as the Architecture and Design, which are dominated by the micro firms (see Figure 6.11), are randomly labelled. Software and computer games is the only sector showing a dispersive pattern relative to the rest of the creative components. As we will discuss further on, when it comes to definition issues, this is the most controversial sector.

6.8 Mutual relationships between core creative sectors

Geographic concentration of creative firms increases the opportunities for them to interrelate, to employ suitable labour, to benefit from common infrastructure and to reduce market uncertainties. In this section we analyse the mutual relationships between specific creative sectors, in order to identify possible co-agglomeration patterns. We test a null hypothesis of random labelling by comparing pairs of creative subcategories.

In the presence of a bivariate point process (with points marked as type *i* and type *j*), at any distance *d*, we have two typologies of events and two distinct types of *K*-functions: the univariate Ripley's *K*-functions for each marked point subset $K_i(d)$ and $K_j(d)$, and the bivariate functions $K_{ij}(d)$ and $K_{ii}(d)$.

Under the null hypothesis of random labelling we have $K_{ij}(d)=K_{ji}(d)=K_{ij}(d)=K_{i}(d$

The null hypothesis is tested by performing the differences between estimators: $\hat{K}_i(d) - \hat{K}_{ij}(d)$ and $\hat{K}_j(d) - \hat{K}_{ij}(d)$. Arbia et al. (2007) argue that

these differences are more informative than the simple difference $\widehat{K}_i(d) \cdot \widehat{K}_j(d)$, suggested by Diggle and Chetwynd (1991), because they allow for a better characterisation of the mutual spatial relationships between the two marked point patterns. For example, when $\widehat{K}_i(d) > \widehat{K}_{ij}(d)$ and $\widehat{K}_j(d) > \widehat{K}_{ji}(d)$ both type i and type j industries show a tendency of segregation within mono-type clusters.

Confidence intervals, at a significance level $\alpha = 0.05$, are generated using Monte Carlo simulations, by keeping firm's location unchanged and by randomly assigning the labels that characterize each sector. The results obtained from the testing of the null hypothesis on all pairs of creative categories are shown in Appendix 4.

Under the hypothesis of random labelling a firm can belong randomly to type *i* or type *j*. In the case of economic activities, this can be interpreted as the existence of conditions that encourage location of one industry rather than the other. To facilitate the interpretation of such a large amount of information, we pinpoint and comment three dominant typologies of attraction-repulsion patterns. We will further comment some significant relationships amongst creative categories, in the light of the literature and by considering the specific characteristic of the study area.

A first, frequent, typology of relationship involves clusters of points of one sector co-existing with points of the second sector that are internally over-dispersed (Figure 6.13). This pattern is observed in the relationship that creative categories in general hold with the Advertising sector and with the Software and computer games sector. In most of the cases clustering distance of the dominant sector is small – between 0 and 15 kilometres, as in the cases of: [Arts, antiquities and crafts; Publishing; Music and performing; Video, film Video, film and photography] versus Advertising; [Arts, antiquities and crafts; Radio and TV] versus Architecture; [Arts, antiquities and crafts; Architecture] versus Software; Publishing versus Design -, or very small - between 0 and 5 kilometres, as in the cases of [Architecture; Radio and TV] versus Advertising; [Arts, antiquities and crafts; Music and performing; Radio and TV; Video, film and photography] versus Design. At higher distances points become randomly labelled. It is, however, important to keep in mind the fact that the number of points on which the estimation is based decreases with the increasing of distance, thus the estimates become less reliable. Clustering distance of the dominating sector is much larger – from 0 up to 30-50 kilometres, for Music and performing; Publishing; Video, Film and Photography] versus Architecture; [Music and performing; Publishing; Radio and TV; Video, Film and Photography] versus Software.

The second typology of relationship is that of the random labelling at

all distances (Figure 6.14). This holds true for: Architecture *versus* Design; Publishing *versus* Video, Film and Photography; Radio and TV *versus* Video, Film and Photography.

The last typology of attraction-repulsion is displayed by the pairs of sectors displaying a clustering pattern of one sector at small distances (less than 20 kilometres) attracting a second sector, which is also self-clustered but at higher distances (Figure 6.15). This type of relationship involves the Arts, antiquities and crafts sector *versus* Publishing; Music and performing arts; Video, film and Photography.

Within the complexity of the urban structure, each creative sector exhibits a proper locational pattern as well as its relationships with other creative sectors. These ties are spatially legible in different contexts and for different types of creative activities.

The advertising industry represents an interesting case to look at. Advertising holds cross-industry links with most of the economic activities, hence with the rest of creative sectors. Advertising is a space-specific industry because, although dominated by international groups, it strongly depends in national markets of regulation and of audience taste (Pratt, 2012). At the local scale this industry is generally characterised by a strong presence of small and micro firms, who have a relatively short life. In this context, physical proximity becomes crucial because enables fluxes of specialized labour.

In the case of Rome we observe the presence of micro firms (up to 10 employees) in the advertising sector that account for more than 70% of the total (Figure 6.4), and a spatial distribution that follows that of the urban imprint in its full extension (Appendix 2: Figure 1). Advertising displays the same spatial behaviour in relation to the 'traditional' cultural industries (Arts, antiques and crafts activities; Music and performing arts; Publishing; Video, film and photography; Radio and TV). This behaviour can be reassumed as follows: cultural industries are concentrated at small distances, while Advertising is internally dispersed at small distances and randomly labelled after. This statistical evidence recalls a spatial arrangement where the 'leading' sector is highly clustered and the 'follower' sector is disposed around it. The 'service' role of Advertising fits well to this spatial arrangement (Appendix 5).

As far as it concerns the relationships with the creative professions, it is interesting to notice the fact that Advertising and Design are randomly labelled at all distances. Advertising shows a slight tendency to cluster at a distance of 0-5 kilometres with respect to the randomly labelled Architecture, and a strong tendency to cluster at a distance of 0-15 kilometres with respect to the internally dispersed Software and computer games (Ap-

Figure 6.13 - Pairwise comparison for "Radio and television" and "Software and computer games".

Figure 6.14 – Pairwise comparison for "Advertising" and "Design".

Figure 6.15 - Pairwise comparison for "Arts, antiques and crafts" and "Video, film and photography".

pendix 4). It is possible to comment these results by looking at some evidences emerging from the analysis of the study area. Despite the fact that Architecture counts eight times more firms if compared to Design (Figure 6.4), these two economic activities have similar spatial behaviours. In analogy with Advertising, they are dominated by small and micro firms and are disposed accordingly to the spatial extension of the urban imprint, thus being less 'site specific'. Random labelling appears well justifiable under these conditions.

This observation is also applicable when looking at the pairwise relationship between Architecture and Design: the un-expectable random labelling between these two sectors is explained by the fact that they are both highly influenced by spatially 'pulverised' activities of self-employed people, whose localization preferences depend more on urban amenities than on mutual relationships.

Design tends to be often within the hypothesis of random labelling when compared to other creative sectors; the only exceptions being Arts, antiques and crafts activities and Publishing, with respect to which it is 'correctly' positioned as a 'follower'.

Another unexpected result is the one of random labelling between Video, film and photography and Radio and TV (Appendix 4). Both sectors are dominated by the presence of medium and large firms (Figure 6.4) and have the tendency to concentrate in precise sectors of the city centre (see Appendix 2: Figures 7; 9). Random labelling maybe due to the reduced spatial extension, but maybe also related to rather imprecise definition of the sectors, related to the fact that the Ateco codes (59.11.0 and 59.12.0) include activities that belong to both sectors (complete list of Ateco codes is in Appendix 1).

Software and computer games constitute one atypical case amongst the creative sectors within the study area. All the pairwise relationships with the other sectors reveal internal dispersion of Software at small distances followed by random labelling (Appendix 4). The behaviour of the functional statistics does not help the interpretation of relationships with other creative sectors. As it can be noticed from Figure 6.4, the sector is dominated by the presence of medium and large firms, it has the highest share in employment and a clear tendency to concentrate in precise sectors of the metropolitan area: in the city centre and in the area between Rome and the Sea (see Appendix 2: Figure 8).

The sector itself and its composition has been object of discussion amongst scholars dealing with creative industries definition criteria (Reeves 2002; Selwood 2002; 2004). It was argued that its inclusion amongst the creative industries was justified by its employment share rather than by its affinity with the creativity (Garnham, 2005). In the present case study we have used the 'inclusive' definition by DCMS, as reported by the NESTA Report (De Propris et al., 2009). The sector definition trough the Ateco codes has revealed some difficulties related to codification problems, not allowing for correct discrimination between subsectors (see Appendix 1). This deficiency hinders from identifying those segments of software production that are clearly related to the creative sector. This question cannot be solved unless precise taxonomies are defined for some 'recent' businesses like the computer games or the new media.

6.9 Core-periphery relationships within creative sectors value chains

Production chains affect industrial clustering. In the case of creative industries, testing for co-localization between content-creation creative activities and related support activities, such as the production and distribution of complementary outputs, would offer evidence about the spatial relationships that creative activities in the different creative economic sectors hold with the support activities in the value chain.

We test a null hypothesis of random labelling by comparing, for each creative category, localization patterns of core creative firms (L1 and L2 layers) with those of the respective service functions (L3, L4 and L5 layers). Detailed distribution of firms and employees in each layer is reported in Appendix 1. Point data is organised according to the previously discussed definition of creative industries adapted for the Italian 5-digit ATECO codes for the observation year 2009. Content creation activities (L1, L2) are marked as 'core' activities, while the rest of firms (L3, L4, L5) are marked as 'support' activities.

Three distinguishable concentration-dispersion patterns can be observed between the core-creative and the service industries for each creative category in the study area:

 Concentration of core creative activities and contextual dispersion of support activities (Architecture; Arts, antiquities and crafts activities; Publishing; Music and performing arts; Video, Film and photography; Radio and TV);

- Concentration of support creative activities and contextual dispersion of core activities (Design);

- Random labelling of core and support activities (Software and computer games).

Figure 6.16 illustrates a case of leader-follower relationship observable amongst centrally located core creative industries in the Radio and TV sec-

tor and its service industries, dispersed around the core. In this case the estimated \hat{D} curve lies above the maximum envelope curve for the distribution of core-creative activities and partially below the minimun envelope curve for the distribution of service activities. Figure 6.17 illustrates an "inverse case" of central clustering of service industries and random labelling of core industries for the Design sector.

Figure 6.17 - Pairwise comparison for "Design" core and service sectors.

Table 6.5 summarises the concentration-dispersion characteristics derived from pairwise comparisons between the core creative industries and the service industries for each creative category. Detailed results are in Appendix 5. Note that Advertising sector is not included, since it is composed only by L1 and L2 type of economic activities.

N. Firms	Concentration	Dispersion	Concentratio	on Peak
11 562	0-50 km			0-50 km
4 108	0-29 km			0-23 km
1 522			0-2 km	
4 921	0-30 km			5-8 km 20-42 km
2 789	0-38 km			0-39 km
322	0-14 km			8-16 km
s 5781				
2 340	0-42 km			0-42 km
	N. Firms 11 562 4 108 1 522 4 921 2 789 322 5 781 2 340	N. Firms Concentration 11 562 0-50 km 4 108 0-29 km 1 522 4 921 0-30 km 2 789 0-38 km 322 0-14 km 5 5 781 2 340 0-42 km	N. Firms Concentration Dispersion 11 562 0-50 km 4 108 0-29 km 1 522 4 921 0-30 km 2 789 0-38 km 322 0-14 km 5 5 781 2 340 0-42 km	N. Firms Concentration Dispersion Concentration 11 562 0-50 km 4 108 0-29 km 1 522 0-2 km 4 921 0-30 km 0-2 km 2 789 0-38 km 322 0-14 km 5 5 781 2 340 0-42 km

Table 6.5 – Concentration-dispersion characteristics between the core-creative and the service industries for each creative category in Greater Rome.

The most striking feature in Table 6.5 is the fact that the service sector of Design is clustered at small distances (0-3 kilometres) while the core sector is randomly labelled (Figure 6.17). This can be explained by the fact that, as already discussed, spatial distribution of Design activities shows no strong intensity peaks or excessive spatial concentration, being the sector dominated by micro firms. On the other hand, value chain includes retailing of fashion and design products, whose tendency to locate in central neighbourhoods is well known. However, interpretation of these results is by no means straightforward. The design sector in the classification scheme based on the DCMS mapping document appears ill assorted when adapted to the Italian case: the Ateco codes do not allow for distinction amongst fashion design and industrial design (these categories are merged in code 74.10.1) and identifiable activities in the value chain include the fashion sector only. Analogies with the Design sector were also noted in the above discussed problematic sector of Software and computer games, which results randomly labelled in relation to its service activities.

Architecture deserves perhaps a separate comment, considering the fact that its supporting sector gathers the largest number both of firms and employees (Figures 6.3 and 6.4). The leader-follower relationship between core and service activities emerges clearly at all distances. This statistical evidence is explained by the fact that service activities within the value chain of Architecture are mainly represented by small but numerous construction firms. In this case the hinterland region is representative in terms of hosting a significant number of economic activities if compared to the central urban agglomeration. In this case it is possible to describe a core creative sector clustered in space and a service sector dispersed internally and disposed around the core.

This observation holds true also for all the 'traditional' cultural sectors: Arts, antiquities and crafts activities; Publishing; Music and performing arts; Video, film and photography; Radio and television. Analysis results for these latest categories perhaps can be interpreted with greater conviction, in the light of the fact that sector boundaries are more consolidated and reliable.

6.10 Conclusive considerations

While looking at the spatial relationships that each creative category holds with the rest of the creative economy, we observe that six out of the nine creative sectors display a pattern of significant concentration. In detail, this holds true for: Advertising; Arts, antiques and crafts; Music and performing arts; Publishing; Radio and television; Video, film and photography. Instead, Software and computer games shows significant dispersion, while Architecture and Design are randomly labelled.

This statistical evidence highlights the fact that macro components of the creative industry, as defined by the DCMS (1998) classification, and similarly by many other national and international institutions, clearly reveal different spatial arrangements: the arts and the media, which are the 'traditional' categories of the 'cultural industry', show a higher tendency to agglomerate if compared to the totality of the creative activities of the city. Creative sectors such as Architecture and Design, which are dominated by the micro firms, are randomly labelled. Software and computer games is the only sector showing a dispersive pattern when compared to the rest of the creative components. These structural spatial characteristics are reflected also in the relationships between different creative sectors and between core-creative activities and their respective support activities.

Pairwise comparisons between creative categories revealed the existence of urban clusters characterised by the co-existence of different creative sectors. Most of the observed joint patterns display a situation of dominance of one sector on the other. This evidence can be interpreted in terms of the existence of a 'leader' sector, clustered in space at small distances, and a 'follower' sector, internally dispersed and spatially disposed around the leader. Typically the leaders are 'traditional' cultural sectors: Arts, antiques and crafts; Publishing; Music and performing arts; Video, film and photography; Radio and television, while followers are creative services such as Advertising and – to a lesser extent – Design.

The observed random labelling amongst Advertising and Design activities is explained by the fact that they both appear to be less 'site specific' if compared to other creative industries, especially if characterised by the presence of medium and large enterprises. Design, in particular, tends often to be within the hypothesis of random labelling when compared to other sectors of the creative economy.

When looking at the pairwise comparisons between the creative sectors and their respective service sectors, the following situation emerges: six out of eight possible pairs of point patterns display a situation of dominance of the creative sector on the service sector. The leader-follower type of relationship is displayed by: Architecture; Arts, antiques and crafts; Publishing; Music and performing arts; Video, Film and photography; Radio and television. This type of relationship between 'core' and 'peripheral' economic activities within the creative value chains can be interpreted in terms of mutual relationships that are influenced by the urban *milieu*. Generally creative firms tend to locate in central neighbourhoods characterized by the high quality of architecture and streetscape and a high density of urban functions. On the other hand, many service activities, despite the requisite for spatial proximity with the core creative sector, are more sensitive to urban real estate values and accessibility to transportation infrastructures.

CHAPTER 7

Conclusions and discussion

Creativity is considered a key competitiveness driver in the knowledgebased economy and one of the most important growth and employment sectors in developed countries playing a major role in the economic regeneration of previously deindustrialised local economies. Creative industries include the media, fashionable consumer goods sectors, services, a wide range of creative professions and collective cultural consumption facilities and account for substantial shares of income and employment. In the last decades, their presence in cities has given to policy makers the opportunity to raising local levels of urban quality and social well-being (Scott, 2004). These strengths are the basis for important potential contributions of creative industries to the 'smart', 'inclusive' and 'sustainable' growth that are placed at the core of Europe 2020 economic strategy.

Understanding the mechanisms through which creative industries interact with the urban context represents an important challenge, in the light of the fact that scientific literature does not provide sufficient empirical evidence to this research topic. In this work the spatial distribution of creative sectors and the relationships with the urban context are analyzed taking as an example Greater Rome, for which it was available a detailed data set of spatially referenced point data, used as input to a statistical model based on Ripley's *K*-function. Pairwise differences between *K*-functions of observed point patterns were computed and compared with simulated confidence bands. A null hypothesis of random labelling was tested upon three conditions: by analysing the spatial distribution of different creative sectors with respect to the rest of the creative industry; by comparing pairs of creative subcategories for the purpose of identifying those revealing mutual attraction; by comparing, for each creative subcategory, localization patterns of creative firms with respect to the localization of respective service functions.

Empirical evidence was provided about the tendency to cluster shown by different creative sectors, about the spatial interaction amongst specific creative activities and about the co-localisation of industries within the value chains. The arts and the media, which are the 'traditional' categories of the 'cultural industry', showed a higher tendency to agglomerate if compared to the totality of the creative activities of the city. Creative sectors such as Architecture and Design, which are dominated by the micro firms, were randomly labelled. Software and computer games was the only sector showing a dispersive pattern when compared to the rest of the creative components. Structural spatial characteristics are reflected also in the relationships amongst different creative sectors. Analysis also showed that core creative sectors have the tendency to cluster in space at small distances while the respective service sectors are dispersed internally and disposed around the core.

This site-specific type of analysis would gain much from the confrontation with empirical evidence obtained in other, different spatial contexts, both at national and international levels. Another consideration to be made when introducing this approach to the study of the creative sector regards the existence of conceptual problems deriving from the lack of a clear-cut definition of what creativity is meant to entail from an economic perspective. This may lead to confusing evidence about the weight of the creative sector and the relative significance of its components, but also to distorted visions on the relationships amongst creative activities and their spatial context. This latest aspect was evidenced also by the analytical results, showing how creative categories whose boundaries were not precisely drawn as a result of definition dilemma or problems with the (SIC) codes not being able to distinguish amongst the components, return statistical evidence that is difficult to interpret.

The claimed success of the creative industries is related to the fact that, differently from the 'Subsidized muse', they are driven by market imperatives to attract the widest possible range of consumers (Granham, 2005). Even though there are conflicting accounts on sectorial data, it is clear that manufacture activities related to fashion, high-end industries and software industries make up the bulk of the economic weight of creative industries (Frontier economics, 2012). The case study in Greater Rome well illustrates this latest aspect, showing how the software sector alone counts for 38% of CCIs employment. This might perhaps be an explanation for the drift that economic policies for cultural and creative industries have taken during the last decade. As we have seen in chapter 3, most of the European funding programmes for creative industries focus on innovation, entrepreneurship and market development, while directly funded culture policies are progressively diminishing.

The quantitative economic irrelevance of arts and culture, evidenced by numerous mapping documents, puts them markedly below their potential to contribute towards the achievement of the European Union's Cohesion policy. Considering the cultural sector as part of the wider creative economy can distort cultural policy objectives, losing sight of the important public benefits provided by culture and of the reasons for public support. This acknowledgement to culture, recognized by the dawn of time, is now undermined by the confusion surrounding the terminology and definitions of cultural and creative. The hype about 'culture as a key ingredient for the functioning of the creative economy' (ESSnet, 2012), by affirming the opposite of what one might think about the cultural-creative relationship (creativity feeds culture), lifts the fog about cultural creativity being distinct from other types of creativity, and being more than simply one further knowledge economy asset.

It is arguable that the explosive development of technological reproduction puts an enormous pressure on the distinction between art as a commodity and art as an independent, sublime creation, whilst the artist is by now replaced by 'the creative', efficient, competitive worker, with pragmatic goals and measurable financial results.

Massive reproduction of cultural products, their branding and the collapse of the individual artist into the collective culture factory, recuperation of ideological adversaries and the absorption of discords into 'a liberal culture of tolerance' are hallmarks of post-modernity. For some, creative economy is the ultimate assault of the market on cultural independence, for others it is another attempt to pursue more profit through more 'creativity', which in turn is just another term for the commercial marketing of culture.

The binomial creative production-cultural consumption involves variable geographies of creativity, '... bringing the symbolic city and urban economy together 'glocally" (Evans, 2009). The creative neighbourhoods are often rooted on fringe industrial and post-industrial areas where they benefit by the lower land rents and by the comparatively loose state control in terms of planning restrictions. The process of gentrification and the emerging of 'cool creative places' in many large and medium size cities of developed countries, counts some excellent examples, such as the bohemian quartiers in Paris and New

York, the squats of Berlin or the Silicon Valley garages, where 'creative innovators' such as Jobs and Gates were able to start their post-modern global fortunes. Rome is still far from developing economically relevant and representative creative clusters, but spontaneous geographies of co-localisation amongst cultural and creative activities are taking place in different parts of the city showing interesting interactions with the urban milieu. Undoubtedly, these developments represent a potential advantage for increasing the economic performance and urban quality of neighborhoods and of the city in general.

Increasingly cities and regions have sought to develop their creative and cultural industries through public intervention, either in response to the decline of other sectors such as industrial manufacturing, or in response to the absence of a perceived economic base in other sectors. In this context, culture is not seen any more as a marginal supplement to everyday leisure; it is rather considered as a pivotal element of the generation of wealth for the new economy (Flew, 2010). Yet, creative industries have rather ephemeral foundations. This may prove quite a challenge when it comes to meaningfully integrating them in territorial planning.

Promoting the development of economic clusters is fashionable in economic policies, both at national and at local levels. The idea behind the development of creative clusters is that cultural industries have strong place-bound characteristics, relying on local production networks. The main trend emerging at national levels is the development of creative clusters fostering innovation through strong links between art, new media and technology, education and businesses. Creative cluster policies are therefore strongly linked to innovation and entrepreneurship policies. There are many ways to conceive and manage economic clusters, ranging from consumption-oriented to production- oriented, from art-based to entertainmentbased. These approaches greatly affect financing and management arrangements. In reality, most of the existing creative cluster initiatives do not come as a result of a clean-cut decision that singles out the best development model; they come rather as a result of a heterogeneous mixture of local initiatives, mixed conceptions of arts as development opportunities in a post-industrial city environment. Therefore, there exist no clear connections between the existing models of creative clusters and the explanations deployed to ground them (Momaas, 2004).

The hypothesis of convergence of economic and cultural policies, applicable to the concept of creative cluster, appears a way of addressing in 'practical' way the complexity of the sector. But may not compensate for the lack of an univocal definition and the impossibility of building up an economic theory on cultural industries.

K. LELO FROM THE SUBSIDIZED MUSE TO CREATIVE INDUSTRIES: CONVERGENCES AND COMPROMISES

Appendix 5

Behaviour of the statistics $\widehat{K}_{c}(d)$ - $\widehat{K}_{cs}(d)$ and $\widehat{K}_{s}(d)$ - $\widehat{K}_{sc}(d)$ (solid line) and of the corresponding min and max envelopes (dashed lines) estimated on the bases of 9999 random labellings.

156

Culture and creativity are considered key competitiveness drivers in advanced knowledge-based post-industrial economies. In the light of the intense academic debate developed around the cultural and creative industries, this book analyses tensions and discussions around the diverging definitions and the effects of different classification schemes in the resulting economic weight of the sector. The second part of the book critically analyses the concept of creative clusters, the relationships of creative industries with the urban milieu and the complex linkages with urban and regional planning and policies. It is argued that difficulties of studying creative clusters from a spatial perspective are related to the existence of conceptual problems as well as to the methodological awkwardness in facing the complexity of this issue. Creative clusters dynamics are illustrated with a case study in Greater Rome.

Keti Lelo is researcher in Economic History at the Department of Business Studies, Roma Tre University, where she teaches Urban history, Urban and regional analysis and Quantitative methods in economical analysis. She is member of the scientific committee of the master "Management, promotion, technological innovation for cultural heritage", where she co-coordinates the module "Knowledge and exploitation of cultural heritage". Her main research areas concern urban economy, urban history and spatial analysis. She is author of scientific publications and coauthor of the blog mapparoma.info, dealing with socio-spatial inequalities.
